# Extended Barzilai-Borwein method for unconstrained minimization problems 

Yasushi Narushima *, Takahiko Wakamatsu ${ }^{\dagger}$ and Hiroshi Yabe ${ }^{\ddagger}$

August 17, 2007 (revised May 20, 2008)

#### Abstract

In 1988, Barzilai and Borwein presented a new choice of step size for the gradient method for solving unconstrained minimization problems. Their method aimed to accelerate the convergence of the steepest descent method. The Barzilai-Borwein method requires few storage locations and inexpensive computations. Therefore, several authors have paid attention to the Barzilai-Borwein method and have proposed some variants to solve large-scale unconstrained minimization problems. In this paper, we extend the Barzilai-Borwein method and establish global and Qsuperlinear convergence properties of the proposed method for minimizing a strictly convex quadratic function. Furthermore, we discuss an application of our method to general objective functions. Finally, some numerical experiments are given.

## 1 Introduction

Recently, we need often to solve large-scale unconstrained minimization problems:

$$
\begin{equation*}
\min f(x), \tag{1.1}
\end{equation*}
$$

where $f: \boldsymbol{R}^{n} \rightarrow \boldsymbol{R}$ is sufficiently smooth and its gradient $g \equiv \nabla f$ is available. Although the Newton method and quasi-Newton methods are effective for solving unconstrained minimization problems, these methods cannot apply directly to large-scale unconstrained minimization problems. Therefore, numerical methods which are based on the steepest descent direction are paid attention to, because they avoid the storage of matrices. We consider the gradient method defined by

$$
\begin{equation*}
x_{k+1}=x_{k}-\frac{1}{\alpha_{k}} g_{k}, \tag{1.2}
\end{equation*}
$$

[^0]where $x_{k}$ is the $k$-th approximation to the optimal solution $x_{*}$ of (1.1), $g_{k}$ is the gradient vector of $f$ at $x_{k}$ and $1 / \alpha_{k}$ is a step size.

The steepest descent method is the simplest gradient method for unconstrained minimization problems. In the steepest descent method, which can be traced back to Cauchy (1847), the following exact step size

$$
\begin{equation*}
\frac{1}{\alpha_{k}}=\underset{\alpha>0}{\operatorname{argmin}} f\left(x_{k}-\frac{1}{\alpha} g_{k}\right) \tag{1.3}
\end{equation*}
$$

is used. Unfortunately, it has been widely known that it converges rather slowly in most cases. This poor behavior is due to the optimal choice of the step size and not to the choice of the steepest descent direction $-g_{k}$. Therefore, several authors dealt with various step sizes to overcome this defect. Barzilai and Borwein [1] incorporated the quasi-Newton property to the gradient method in order to obtain the second order information of the objective function $f(x)$. Specifically, they approximated the Hessian $\nabla^{2} f\left(x_{k}\right)$ by $\alpha_{k} I$ and based on the secant condition, they considered the following minimization problem:

$$
\alpha_{k}=\underset{\alpha \in R}{\arg \min }\left\|\alpha I s_{k-1}-y_{k-1}\right\|
$$

where $s_{k-1}=x_{k}-x_{k-1}, y_{k-1}=g_{k}-g_{k-1}$ and $\|\cdot\|$ denotes the Euclidean norm. This minimum value is defined by

$$
\begin{equation*}
\alpha_{k}=\frac{s_{k-1}^{T} y_{k-1}}{s_{k-1}^{T} s_{k-1}} \tag{1.4}
\end{equation*}
$$

The gradient method with (1.4) is called the Barzilai-Borwein method.
Moreover, Dai, Hager, Schittkowski and Zhang [4] presented numerical results by using

$$
\begin{equation*}
\alpha_{k}=\frac{s_{\nu(k)}^{T} y_{\nu(k)}}{s_{\nu(k)}^{T} s_{\nu(k)}} \tag{1.5}
\end{equation*}
$$

and

$$
\nu(k)=M_{c}\left\lfloor\frac{k-1}{M_{c}}\right\rfloor,
$$

where for $r \in \boldsymbol{R},\lfloor r\rfloor$ denotes the largest integer $j$ such that $j \leq r$ and $M_{c}$ is a positive integer. The gradient method with (1.5) is called the cyclic Barzilai-Borwein method. Numerical results in [4] suggested that their method performed better than the BarzilaiBorwein method did. On the other hand, Raydan [17] proposed the globally convergent Barzilai-Borwein method by using nonmonotone line search by Grippo et al. [10].

Many researchers study the gradient method for minimizing a strictly convex quadratic function, namely,

$$
\begin{equation*}
\min \quad f(x)=\frac{1}{2} x^{T} A x-b^{T} x \tag{1.6}
\end{equation*}
$$

where $A \in \boldsymbol{R}^{n \times n}$ is a symmetric positive definite matrix and $b \in \boldsymbol{R}^{n}$ is a given vector. For an application of the Barzilai-Borwein method to problem (1.6), Raydan [16] established global convergence and Dai and Liao [5] proved R-linear rate of convergence. Friedlander, Martinez, Molina and Raydan [9] proposed a new gradient method with retards, in which $\alpha_{k}$ is defined by

$$
\begin{align*}
\alpha_{k} & =\frac{g_{\nu(k)}^{T} A^{\rho(k)+1} g_{\nu(k)}}{g_{\nu(k)}^{T} A^{\rho(k)} g_{\nu(k)}}  \tag{1.7}\\
\nu(k) & \in\{k, k-1, \ldots, \max \{0, k-m\}\}
\end{align*}
$$

and

$$
\rho(k) \in\left\{q_{1}, \ldots, q_{m}\right\}
$$

where $m$ is a positive integer, and $q_{1}, \ldots, q_{m}(\geq-2)$ are integers. They established its global convergence for problem (1.6) and proved the Q-superlinear rate of convergence in the special case.

The Barzilai-Borwein method and its related methods are reviewed by Dai and Yuan [6] and Fletcher [8].

In this paper, we propose a new step size by extending (1.7). This paper is organized as follows. In Section 2, we propose a new step size and present the algorithm of our method. In Section 3, we show the global convergence property of our method. Moreover using the Dennis-Moré condition, we discuss Q-superlinear convergence in the special case. In Section 4, we consider the extension of the proposed method to general functions by using nonmonotone line search. We establish its global and Q-superlinear convergence properties. Finally, some numerical results are given in Section 5.

## 2 Algorithm of extended Barzilai-Borwein method for quadratic functions

In this section, we consider an extension of the Barzilai-Borwein method for minimizing strictly convex quadratic function (1.6). Following Friedlander et al.[9], we propose a new step size for (1.2) as follows:

$$
\begin{align*}
\alpha_{k} & =\sum_{i=1}^{\ell} \phi_{i} \frac{g_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)+1} g_{\nu_{i}(k)}}{g_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)} g_{\nu_{i}(k)}}  \tag{2.1}\\
\phi_{i} & \geq 0, \quad \sum_{i=1}^{\ell} \phi_{i}=1, \\
\nu_{i}(k) & \in\{k, k-1, \ldots, \max \{0, k-m\}\}
\end{align*}
$$

and

$$
\rho_{i}(k) \in\left\{q_{1}, \ldots, q_{m}\right\}
$$

where $\ell$ and $m$ are positive integers, and $q_{1}, \ldots, q_{m}$ are integers. We call this gradient method the extended Barzilai-Borwein method.

Now we describe the algorithm of our method as follows.

## Algorithm 1 (Algorithm EBB)

Step 0. Given $x_{0} \in \boldsymbol{R}^{n}$, set $k=0$. If $g_{0}=0$, then stop. Otherwise go to Step 1 .
Step 1. Compute $\alpha_{k}$ by (2.1).
Step 2. Let $x_{k+1}=x_{k}-\frac{1}{\alpha_{k}} g_{k}$. If $g_{k+1}=0$, then stop.
Step 3. Let $k:=k+1$ and go to Step 1.
Since $\alpha_{k}$ is the Rayleigh quotient of the symmetric positive definite matrix $A$, the following relation holds

$$
\begin{equation*}
0<\lambda_{\min } \leq \alpha_{k} \leq \lambda_{\max } \quad \text { for all } k, \tag{2.2}
\end{equation*}
$$

where $\lambda_{\min }$ and $\lambda_{\max }$ are respectively the smallest and largest eigenvalues of $A$. Using (1.2) and the fact that $g_{k}=A x_{k}-b$, we have

$$
\begin{equation*}
s_{k}=-\frac{1}{\alpha_{k}} g_{k} \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
y_{k}=A s_{k} . \tag{2.4}
\end{equation*}
$$

If $\nu_{i}(k) \neq k$ for all $k$, expressions (2.3) and (2.4) give

$$
\begin{align*}
\alpha_{k} & =\sum_{i=1}^{\ell} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)+1} s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)} s_{\nu_{i}(k)}}  \tag{2.5}\\
& =\sum_{i=1}^{\ell} \phi_{i} \frac{y_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)-1} y_{\nu_{i}(k)}^{T}}{y_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)-2} y_{\nu_{i}(k)}} .
\end{align*}
$$

We note that if $\ell=1, \nu_{1}(k)=k$ and $\rho_{1}(k)=0$ for all $k$, (2.1) becomes

$$
\begin{equation*}
\alpha_{k}=\frac{g_{k}^{T} A g_{k}}{g_{k}^{T} g_{k}} \tag{2.6}
\end{equation*}
$$

which implies the steepest descent method. On the other hand, if $\ell=1, \nu_{1}(k)=$ $\max \{0, k-1\}$ and $\rho_{1}(k)=0$ for all $k$, using (2.4) and (2.5) yields

$$
\alpha_{k}=\frac{s_{k-1}^{T} A s_{k-1}}{s_{k-1}^{T} s_{k-1}}=\frac{s_{k-1}^{T} y_{k-1}}{s_{k-1}^{T} s_{k-1}},
$$

which is the Barzilai-Borwein method (1.4). Moreover, if $\ell=1$ and $q_{j} \geq-2$, then by (2.1), we see that

$$
\alpha_{k}=\frac{g_{\nu_{1}(k)}^{T} A^{\rho_{1}(k)+1} g_{\nu_{1}(k)}}{g_{\nu_{1}(k)}^{T} A^{\rho_{1}(k)} g_{\nu_{1}(k)}}
$$

which is the gradient method with retards (1.7). Therefore, (2.1) is the extension of (1.4) and (1.7).

## 3 Convergence analysis for quadratic functions

In this section, we consider convergence properties of Algorithm EBB.

### 3.1 Global convergence property

In this subsection, we establish global convergence of the extended Barzilai-Borwein method for problem (1.6). Let $\left\{x_{k}\right\}$ be the sequence generated by Algorithm EBB and let $e_{k}=x_{*}-x_{k}$. Using the fact that $g_{k}=A x_{k}-b$ and $b=A x_{*}$, we get

$$
\begin{align*}
g_{k} & =A x_{k}-b \\
& =A x_{k}-A x_{*} \\
& =-A e_{k} . \tag{3.1}
\end{align*}
$$

By (2.1) and (3.1), $\alpha_{k}$ can be written by

$$
\begin{equation*}
\alpha_{k}=\sum_{i=1}^{\ell} \phi_{i} \frac{g_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)+1} g_{\nu_{i}(k)}}{g_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)} g_{\nu_{i}(k)}}=\sum_{i=1}^{\ell} \phi_{i} \frac{e_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)+3} e_{\nu_{i}(k)}}{e_{\nu_{i}(k)}^{T} A^{\rho_{i}(k)+2} e_{\nu_{i}(k)}} . \tag{3.2}
\end{equation*}
$$

Let $\left\{\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\right\}\left(\lambda_{1} \leq \lambda_{2} \leq \ldots \leq \lambda_{n}\right)$ be eigenvalues of $A$ and let $\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ be orthonormal eigenvectors of $A$ associated with the eigenvalues $\left\{\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\right\}$. For the initial error $e_{0}$, there exist constants $d_{1}^{0}, d_{2}^{0}, \ldots, d_{n}^{0}$ such that

$$
\begin{equation*}
e_{0}=\sum_{j=1}^{n} d_{j}^{0} v_{j} . \tag{3.3}
\end{equation*}
$$

It follows from (3.1) that

$$
\begin{align*}
e_{k+1} & =x_{*}-x_{k+1} \\
& =e_{k}+\frac{1}{\alpha_{k}} g_{k} \\
& =\frac{1}{\alpha_{k}}\left(\alpha_{k} I-A\right) e_{k} \tag{3.4}
\end{align*}
$$

Thus, using (3.3) and (3.4) yields

$$
\begin{aligned}
e_{k+1} & =\prod_{i=0}^{k} \frac{1}{\alpha_{i}}\left(\alpha_{i} I-A\right) e_{0} \\
& =\left\{\prod_{i=0}^{k} \frac{1}{\alpha_{i}}\left(\alpha_{i} I-A\right)\right\}\left(\sum_{j=1}^{n} d_{j}^{0} v_{j}\right) \\
& =\sum_{j=1}^{n} d_{j}^{0}\left\{\prod_{i=0}^{k} \frac{1}{\alpha_{i}}\left(\alpha_{i} I-A\right)\right\} v_{j} \\
& =\sum_{j=1}^{n} d_{j}^{0}\left\{\prod_{i=0}^{k} \frac{1}{\alpha_{i}}\left(\alpha_{i}-\lambda_{j}\right)\right\} v_{j} .
\end{aligned}
$$

Therefore, defining

$$
\begin{equation*}
d_{j}^{k+1}=\prod_{i=0}^{k}\left(\frac{\alpha_{i}-\lambda_{j}}{\alpha_{i}}\right) d_{j}^{0} \quad \text { for } \quad j=1, \ldots, n, \tag{3.5}
\end{equation*}
$$

we have

$$
\begin{equation*}
e_{k+1}=\sum_{j=1}^{n} d_{j}^{k+1} v_{j} \quad \text { for all } k, \tag{3.6}
\end{equation*}
$$

which implies the relation

$$
\begin{equation*}
d_{j}^{k+1}=\left(\frac{\alpha_{k}-\lambda_{j}}{\alpha_{k}}\right) d_{j}^{k} \quad \text { for } \quad j=1, \ldots, n . \tag{3.7}
\end{equation*}
$$

Moreover, by (2.2), the following relations hold for any $k$

$$
\begin{equation*}
\left|1-\frac{\lambda_{i}}{\alpha_{k}}\right| \leq \frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}} \quad(i=1, \ldots, n) . \tag{3.8}
\end{equation*}
$$

In order to establish global convergence of Algorithm EBB, we give some lemmas. The following lemma corresponds to Lemma 2.1 in Friedlander et al. [9] and the proof is exactly the same as that of Lemma 2.1 in [9], so we omit it.

Lemma 1 The sequence $\left\{d_{1}^{k}\right\}$ converges to zero $Q$-linearly with convergence factor $\hat{c}_{1}=$ $1-\left(\lambda_{1} / \lambda_{n}\right)$.

The following lemma corresponds to Lemma 2.2 in Friedlander et al. [9].
Lemma 2 If the sequences $\left\{d_{1}^{k}\right\},\left\{d_{2}^{k}\right\}, \ldots,\left\{d_{p-1}^{k}\right\}$ converge to zero for a fixed integer $p(2 \leq$ $p \leq n$ ), then

$$
\liminf _{k \rightarrow \infty}\left|d_{p}^{k}\right|=0
$$

holds.

Proof. In order to prove this lemma by contradiction, we suppose that there exists a positive constant $\varepsilon$ such that

$$
\begin{equation*}
\left(d_{p}^{k}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2} \geq \varepsilon \quad \text { for all } k . \tag{3.9}
\end{equation*}
$$

Then, by (3.2), (3.6) and the orthonormality of the eigenvectors $\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$, we obtain

$$
\begin{equation*}
\alpha_{k}=\sum_{i=1}^{\ell} \phi_{i} \frac{\left(\sum_{j=1}^{n} d_{j}^{\nu_{i}(k)} v_{j}\right)^{T} A^{\rho_{i}(k)+3}\left(\sum_{j=1}^{n} d_{j}^{\nu_{i}(k)} v_{j}\right)}{\left(\sum_{j=1}^{n} d_{j}^{\nu_{i}(k)} v_{j}\right)^{T} A^{\rho_{i}(k)+2}\left(\sum_{j=1}^{n} d_{j}^{\nu_{i}(k)} v_{j}\right)}=\sum_{i=1}^{\ell} \phi_{i} \frac{\sum_{j=1}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+3}}{\sum_{j=1}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} . \tag{3.10}
\end{equation*}
$$

Since the sequences $\left\{d_{1}^{k}\right\},\left\{d_{2}^{k}\right\}, \ldots,\left\{d_{p-1}^{k}\right\}$ converge to zero, there exists a sufficiently large $\hat{k}$ such that

$$
\begin{equation*}
\sum_{j=1}^{p-1}\left(d_{j}^{k}\right)^{2} \max _{1 \leq u \leq m} \lambda_{j}^{q_{u}+2} \leq \frac{1}{2} \varepsilon \quad \text { for } \text { all } k \geq \hat{k} \tag{3.11}
\end{equation*}
$$

By (3.10) and (3.11), we have for all $k \geq \hat{k}+m$

$$
\begin{align*}
\alpha_{k} & =\sum_{i=1}^{\ell} \phi_{i} \frac{\sum_{j=1}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+3}}{\sum_{j=1}^{n}\left(d_{j}^{\nu_{i}}(k)\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} \\
& \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2} \lambda_{j}}{\sum_{j=1}^{p-1}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}+\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} \\
& \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p} \sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}}{\frac{1}{2} \varepsilon+\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} . \tag{3.12}
\end{align*}
$$

Since from (3.9) we get

$$
\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2} \geq\left(d_{p}^{\nu_{i}(k)}\right)^{2} \lambda_{p}^{\rho_{i}(k)+2} \geq\left(d_{p}^{\nu_{i}(k)}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2} \geq \varepsilon \quad \text { for } \quad \text { all } k \geq \hat{k}+m
$$

(2.2) and (3.12) yield for all $k \geq \hat{k}+m$

$$
\begin{aligned}
\lambda_{n} \geq \alpha_{k} & \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p} \sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}}{\frac{1}{2} \varepsilon+\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} \\
& =\sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p}}{\frac{1}{2} \varepsilon\left(1 / \sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}\right)+1} \\
& \geq \frac{2}{3} \lambda_{p},
\end{aligned}
$$

which implies

$$
\begin{equation*}
\left|1-\frac{\lambda_{p}}{\alpha_{k}}\right| \leq \max \left(\frac{1}{2}, 1-\frac{\lambda_{p}}{\lambda_{n}}\right) \leq \max \left(\frac{1}{2}, 1-\frac{\lambda_{1}}{\lambda_{n}}\right) \quad \text { for all } k \geq \hat{k}+m \tag{3.13}
\end{equation*}
$$

Using (3.7) and (3.13) yields

$$
\left|d_{p}^{k+1}\right|=\left|1-\frac{\lambda_{p}}{\alpha_{k}}\right|\left|d_{p}^{k}\right| \leq \hat{c}_{2}\left|d_{p}^{k}\right| \quad \text { for all } k \geq \hat{k}+m
$$

with

$$
\hat{c}_{2}=\max \left(\frac{1}{2}, 1-\frac{\lambda_{1}}{\lambda_{n}}\right)<1 .
$$

Because this conclusion contradicts the hypothesis (3.9), we find that the lemma is true.

By using Lemmas 1 and 2, we can prove the next theorem,
Theorem 1 Let $\left\{x_{k}\right\}$ be the sequence generated by Algorithm EBB for problem (1.6) and let $x_{*}$ be the unique minimizer of $f$. Then, either $x_{j}=x_{*}$ for some finite $j$, or the sequence $\left\{x_{k}\right\}$ converges to $x_{*}$.

Proof. If there exists a finite integer $j$ such that $x_{j}=x_{*}$, then this theorem is true. Hence we consider the case $x_{k} \neq x_{*}$ for all $k$ to prove this theorem and it suffices to prove that the sequence $\left\{e_{k}\right\}$ converges to the zero. It follows from (3.6) and the orthonormality of the eigenvectors that

$$
\begin{equation*}
\left\|e_{k}\right\|^{2}=\sum_{i=1}^{n}\left(d_{i}^{k}\right)^{2} \tag{3.14}
\end{equation*}
$$

holds. We note that the sequence of the errors $\left\{e_{k}\right\}$ converges to zero if and only if each one of the sequences $\left\{d_{i}^{k}\right\}$ for $i=1, \ldots, n$ converges to zero. Since Lemma 1 shows that $\left\{d_{1}^{k}\right\}$ converges to zero, we prove that $\left\{d_{p}^{k}\right\}$ converges to zero for $2 \leq p \leq n$ by induction on $p$. For this purpose, we let $p$ be any integer from this interval and we assume that $\left\{d_{1}^{k}\right\}, \ldots,\left\{d_{p-1}^{k}\right\}$ all tend to zero. Then for any given $\varepsilon>0$, there exists a sufficiently large $\hat{k}$ such that

$$
\begin{equation*}
\sum_{j=1}^{p-1}\left(d_{j}^{k}\right)^{2} \max _{1 \leq u \leq m} \lambda_{j}^{q_{u}+2} \leq \frac{1}{2} \varepsilon \quad \text { for } \text { all } k \geq \hat{k} \tag{3.15}
\end{equation*}
$$

As shown in (3.12), we have

$$
\begin{equation*}
\alpha_{k} \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p} \sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}}{\frac{1}{2} \varepsilon+\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} \quad \text { for } \text { all } k \geq \hat{k}+m \tag{3.16}
\end{equation*}
$$

By Lemma 2 , there exists a $k^{\prime}(\geq \hat{k}+m)$ such that

$$
\begin{equation*}
\min _{0 \leq t \leq m}\left(d_{p}^{k^{\prime}-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}<\varepsilon \tag{3.17}
\end{equation*}
$$

Let $\left\{\bar{k}_{r}\right\}\left(\geq k^{\prime}\right)$ be a sequence such that the following inequalities hold

$$
\min _{0 \leq t \leq m}\left(d_{p}^{\bar{k}_{r}-1-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}<\varepsilon
$$

and

$$
\min _{0 \leq t \leq m}\left(d_{p}^{\bar{k}_{r}-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2} \geq \varepsilon,
$$

and let $\varphi\left(\bar{k}_{r}\right)$ be the first integer greater than $\bar{k}_{r}$ for which the following inequality holds

$$
\min _{0 \leq t \leq m}\left(d_{p}^{\varphi\left(\bar{k}_{r}\right)-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}<\varepsilon
$$

By taking Lemma 2 into account, it suffices to consider the following two cases (i) and (ii).

Case (i). If the sequence $\left\{\bar{k}_{r}\right\}$ is a finite sequence, then there exists a sufficiently large $k^{\prime \prime}\left(\geq k^{\prime}\right)$ such that

$$
\begin{equation*}
\min _{0 \leq t \leq m}\left(d_{p}^{k-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}=\left(d_{p}^{k-t^{\prime}}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}<\varepsilon \quad \text { for any } k \geq k^{\prime \prime} \tag{3.18}
\end{equation*}
$$

where $t^{\prime}$ is an integer which depends on $k$. By (3.7), (3.8) and (3.18), we have

$$
\begin{align*}
\left(d_{p}^{k}\right)^{2} & =\left(\prod_{i=k-t^{\prime}}^{k-1} \frac{\alpha_{i}-\lambda_{p}}{\alpha_{i}}\right)^{2}\left(d_{p}^{k-t^{\prime}}\right)^{2} \\
& \leq\left(\prod_{i=k-t^{\prime}}^{k-1} \frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2}\left(d_{p}^{k-t^{\prime}}\right)^{2} \\
& \leq \max \left(\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2 m}, 1\right)\left(d_{p}^{k-t^{\prime}}\right)^{2} \\
& \leq \max \left(\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2 m}, 1\right) \frac{\varepsilon}{\min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}} \tag{3.19}
\end{align*}
$$

which implies that for all $k \geq k^{\prime \prime}$, the following holds

$$
\begin{equation*}
\left(d_{p}^{k}\right)^{2} \leq \hat{c}_{3} \varepsilon \tag{3.20}
\end{equation*}
$$

with

$$
\hat{c}_{3}=\max \left(\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2 m}, 1\right) \frac{1}{\min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}}
$$

Case (ii). If the sequence $\left\{\bar{k}_{r}\right\}$ is an infinite sequence, by the definitions of $\left\{\bar{k}_{r}\right\}$ and $\left\{\varphi\left(\bar{k}_{r}\right)\right\}$, we get

$$
\begin{equation*}
\min _{0 \leq t \leq m}\left(d_{p}^{k-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2} \geq \varepsilon \quad \text { for } \quad k\left(\bar{k}_{r} \leq k \leq \varphi\left(\bar{k}_{r}\right)-1\right) \tag{3.21}
\end{equation*}
$$

and

$$
\begin{equation*}
\min _{0 \leq t \leq m}\left(d_{p}^{k-t}\right)^{2} \min _{1 \leq u \leq m} \lambda_{p}^{q_{u}+2}<\varepsilon \quad \text { for } \quad k\left(\varphi\left(\bar{k}_{r}\right) \leq k \leq \bar{k}_{r+1}-1\right) . \tag{3.22}
\end{equation*}
$$

As shown in (3.18), (3.19) and (3.20), inequality (3.22) yields

$$
\begin{equation*}
\left(d_{p}^{k}\right)^{2} \leq \hat{c}_{3} \varepsilon \quad \text { for } \quad k\left(\varphi\left(\bar{k}_{r}\right) \leq k \leq \bar{k}_{r+1}-1\right) \tag{3.23}
\end{equation*}
$$

By (3.16) and (3.21), we have for all $k\left(\bar{k}_{r} \leq k \leq \varphi\left(\bar{k}_{r}\right)-1\right)$

$$
\begin{align*}
\lambda_{n} \geq \alpha_{k} & \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p} \sum_{j=p}^{n}\left(d_{j}^{\nu_{j}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}}{\frac{1}{2} \varepsilon+\sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}} \\
& =\sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p}}{\frac{1}{2} \varepsilon\left(1 / \sum_{j=p}^{n}\left(d_{j}^{\nu_{i}(k)}\right)^{2} \lambda_{j}^{\rho_{i}(k)+2}\right)+1} \\
& \geq \sum_{i=1}^{\ell} \phi_{i} \frac{\lambda_{p}}{\frac{1}{2} \varepsilon\left(1 /\left(d_{p}^{\nu_{i}(k)}\right)^{2} \lambda_{p}^{\rho_{i}(k)+2}\right)+1} \\
& \geq \frac{2}{3} \lambda_{p} . \tag{3.24}
\end{align*}
$$

As shown in (3.13), inequality (3.24) implies

$$
\left|1-\frac{\lambda_{p}}{\alpha_{k}}\right| \leq \max \left(\frac{1}{2}, 1-\frac{\lambda_{p}}{\lambda_{n}}\right) \leq \max \left(\frac{1}{2}, 1-\frac{\lambda_{1}}{\lambda_{n}}\right)<1,
$$

so using (3.7) yields

$$
\begin{equation*}
\left|d_{p}^{k+1}\right|=\left|1-\frac{\lambda_{p}}{\alpha_{k}}\right|\left|d_{p}^{k}\right| \leq\left|d_{p}^{k}\right| \quad \text { for } \quad k\left(\bar{k}_{r} \leq k \leq \varphi\left(\bar{k}_{r}\right)-1\right) \tag{3.25}
\end{equation*}
$$

Thus, by (3.25), (3.7) and (3.8), we have

$$
\begin{array}{r}
\left(d_{p}^{k}\right)^{2} \leq\left(d_{p}^{\bar{k}_{r}}\right)^{2} \leq\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2}\left(d_{p}^{\bar{k}_{r}-1}\right)^{2} \leq\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2} \hat{c}_{3} \varepsilon=\hat{c}_{4} \varepsilon \\
\text { for } k\left(\bar{k}_{r} \leq k \leq \varphi\left(\bar{k}_{r}\right)\right)
\end{array}
$$

with

$$
\hat{c}_{4}=\left(\frac{\lambda_{n}-\lambda_{1}}{\lambda_{1}}\right)^{2} \hat{c}_{3} .
$$

The last inequality can be obtained by using (3.23).
By summarizing the cases (i) and (ii), we obtain for all $k\left(\geq k^{\prime \prime}\right)$

$$
\left(d_{p}^{k}\right)^{2} \leq \hat{c}_{5} \varepsilon
$$

with

$$
\hat{c}_{5}=\max \left(\hat{c}_{3}, \hat{c}_{4}\right) .
$$

Since $\varepsilon>0$ can be chosen arbitrarily small, we deduce $\lim _{k \rightarrow \infty}\left|d_{p}^{k}\right|=0$ as required. Therefore, by induction on $p$ and (3.14), $\lim _{k \rightarrow \infty}\left|d_{i}^{k}\right|=0$ for $i=1, \ldots, n$ and $\lim _{k \rightarrow \infty}\left\|e_{k}\right\|=0$ hold. This completes the proof.

Note that Theorem 1 is the extension of Theorem 2.1 in Friedlander et al. [9].

### 3.2 Q-superlinear convergence

In this subsection, we analyze the local behavior of Algorithm EBB. To this end, we deal with the case where $\nu_{i}(k) \neq k$ and $\rho_{i}(k)$ does not depend on $k$ in (2.1). For simplicity, we denote $\rho_{i}(k)$ by $r_{i}$. From (2.5), we have

$$
\begin{equation*}
\alpha_{k}=\sum_{i=1}^{\ell} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} A^{r_{i}+1} s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} A^{r_{i}} s_{\nu_{i}(k)}} \tag{3.26}
\end{equation*}
$$

where $\ell$ and $m$ are positive integers, $r_{j}(j=1, \ldots, \ell)$ are integers, $\sum_{i=1}^{\ell} \phi_{i}=1$ and

$$
\phi_{i} \geq 0, \quad \nu_{i}(k) \in\{k-1, \ldots, \max \{0, k-m\}\} \quad \text { for } i=1, \ldots, \ell .
$$

In order to establish the Q-superlinear convergence property of our method, we introduce the following well-known lemma for general unconstrained minimization problems, which was proved by Dennis and Moré [7].

Lemma 3 (Dennis-Moré condition) Let $F: \boldsymbol{R}^{n} \rightarrow \boldsymbol{R}$ be a twice continuously differentiable function in an open convex set $D \subset \boldsymbol{R}^{n}$. Consider the minimization problem of $F(x)$. Assume that for some $\hat{x}$ in $D, \nabla^{2} F(\hat{x})$ is nonsingular. Let $\left\{B_{k}\right\}$ be a sequence of nonsingular $n \times n$ matrices. Suppose that for some $x_{0}$ in $D$ the sequence $\left\{x_{k}\right\}$ generated by

$$
x_{k+1}=x_{k}-B_{k}^{-1} \nabla F\left(x_{k}\right), \quad k=0,1,2, \cdots
$$

remains in $D$ and converges to $\hat{x}$. Then $\left\{x_{k}\right\}$ converges $Q$-superlinearly to $\hat{x}$ and $\nabla F(\hat{x})=$ 0 if and only if

$$
\lim _{k \rightarrow \infty} \frac{\left\|\left[B_{k}-\nabla^{2} F(\hat{x})\right]\left(x_{k+1}-x_{k}\right)\right\|}{\left\|x_{k+1}-x_{k}\right\|}=0 .
$$

By using Lemma 3, we can prove the next theorem.
Theorem 2 Let $\left\{x_{k}\right\}$ be the sequence generated by Algorithm EBB with (3.26) for problem (1.6). Assume that the sequence $\left\{s_{k} /\left\|s_{k}\right\|\right\}$ is convergent, that is, there exists $s \in \boldsymbol{R}^{n}$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{s_{k}}{\left\|s_{k}\right\|}=s \quad \text { and } \quad\|s\|=1 \tag{3.27}
\end{equation*}
$$

Then $s$ becomes an eigenvector of $A$ with the eigenvalue $s^{T} A s$ and

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \alpha_{k}=s^{T} A s \tag{3.28}
\end{equation*}
$$

Moreover, the sequence $\left\{x_{k}\right\}$ converges $Q$-superlinearly to $x_{*}$.

Proof. It follows immediately from Theorem 1 that $\left\{x_{k}\right\}$ converges to $x_{*}$. Thus, we need only show that $\left\{x_{k}\right\}$ converges Q -superlinearly to $x_{*}$.

Using $\lambda_{i}$ and $v_{i}(i=1, . ., n)$ given in Subsection 3.1, we define

$$
A^{r / 2}=\sum_{i=1}^{n} \lambda_{i}^{r / 2} v_{i} v_{i}^{T},
$$

where $r$ is any integer. This implies that

$$
\left(A^{r_{i} / 2}\right)^{2}=A^{r_{i}} \quad \text { for } \quad i=1, \ldots, \ell
$$

Then, equation (3.26) can be written by

$$
\begin{equation*}
\alpha_{k}=\sum_{i=1}^{\ell} \phi_{i}\left(\frac{A^{r_{i} / 2} s_{\nu_{i}(k)}}{\left\|A^{r_{i} / 2} s_{\nu_{i}(k)}\right\|}\right)^{T} A\left(\frac{A^{r_{i} / 2} s_{\nu_{i}(k)}}{\left\|A^{r_{i} / 2} s_{\nu_{i}(k)}\right\|}\right) . \tag{3.29}
\end{equation*}
$$

For simplicity, we define

$$
\hat{s}^{(i)}=\frac{A^{r_{i} / 2} s}{\left\|A^{r_{i} / 2} s\right\|} \quad \text { for } \quad i=1, \ldots, \ell
$$

and

$$
\alpha=\sum_{i=1}^{\ell} \phi_{i} \hat{s}^{(i) T} A \hat{s}^{(i)} .
$$

From the fact that $\nu_{i}(k) \geq k-m(i=1, \ldots, \ell)$, we get

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{A^{r_{i} / 2} s_{\nu_{i}(k)}}{\left\|A^{r_{i} / 2} s_{\nu_{i}(k)}\right\|}=\hat{s}^{(i)} \quad \text { for } \quad i=1, \ldots, \ell . \tag{3.30}
\end{equation*}
$$

Therefore, by (3.29) and (3.30), we have

$$
\begin{aligned}
\lim _{k \rightarrow \infty} \alpha_{k} & =\lim _{k \rightarrow \infty} \sum_{i=1}^{\ell} \phi_{i}\left(\frac{A^{r_{i} / 2} s_{\nu_{i}(k)}}{\left\|A^{r_{i} / 2} s_{\nu_{i}(k)}\right\|}\right)^{T} A\left(\frac{A^{r_{i} / 2} s_{\nu_{i}(k)}}{\left\|A^{r_{i} / 2} s_{\nu_{i}(k)}\right\|}\right) \\
& =\sum_{i=1}^{\ell} \phi_{i} \hat{s}^{(i) T} A \hat{s}^{(i)} \\
& =\alpha .
\end{aligned}
$$

It follows from (2.3), (3.1) and (3.4) that

$$
s_{k+1}=-\frac{1}{\alpha_{k+1}}\left(A-\alpha_{k} I\right) s_{k} .
$$

Premultiplying this equation by $A^{r_{i} / 2}$, we have

$$
A^{r_{i} / 2} s_{k+1}=-\frac{1}{\alpha_{k+1}}\left(A-\alpha_{k} I\right) A^{r_{i} / 2} s_{k} \quad \text { for } \quad i=1, \ldots, \ell
$$

We normalize the above equation, and we get

$$
\frac{A^{r_{i} / 2} s_{k+1}}{\left\|A^{r_{i} / 2} s_{k+1}\right\|}=-\frac{\left(A-\alpha_{k} I\right) A^{r_{i} / 2} s_{k} /\left\|A^{r_{i} / 2} s_{k}\right\|}{\left\|\left(A-\alpha_{k} I\right) A^{r_{i} / 2} s_{k} /\right\| A^{r_{i} / 2} s_{k}\| \|} \quad \text { for } \quad i=1, \ldots, \ell
$$

which implies

$$
\left\|\left(A-\alpha_{k} I\right) \frac{A^{r_{i} / 2} s_{k}}{\left\|A^{r_{i} / 2} s_{k}\right\|}\right\| \frac{A^{r_{i} / 2} s_{k+1}}{\left\|A^{r_{i} / 2} s_{k+1}\right\|}=-\left(A-\alpha_{k} I\right) \frac{A^{r_{i} / 2} s_{k}}{\left\|A^{r_{i} / 2} s_{k}\right\|} \quad \text { for } \quad i=1, \ldots, \ell
$$

Taking limits on both sides of this equation, we have

$$
\left\|(A-\alpha I) \hat{s}^{(i)}\right\| \hat{s}^{(i)}=-(A-\alpha I) \hat{s}^{(i)} \quad \text { for } \quad i=1, \ldots, \ell
$$

Furthermore, premultiplying this equation by $\hat{s}^{(i) T}$ yields

$$
\begin{equation*}
\left\|(A-\alpha I) \hat{s}^{(i)}\right\|=-\hat{s}^{(i) T} A \hat{s}^{(i)}+\alpha \text { for } i=1, \ldots, \ell . \tag{3.31}
\end{equation*}
$$

Thus, by (3.31) and the fact that $\sum_{i=1}^{\ell} \phi_{i}=1$, we have

$$
\begin{aligned}
\sum_{i=1}^{\ell} \phi_{i}\left\|(A-\alpha I) \hat{s}^{(i)}\right\| & =-\sum_{i=1}^{\ell} \phi_{i} \hat{s}^{(i) T} A \hat{s}^{(i)}+\sum_{i=1}^{\ell} \phi_{i} \alpha \\
& =-\sum_{i=1}^{\ell} \phi_{i} \hat{s}^{(i) T} A \hat{s}^{(i)}+\alpha \\
& =0 .
\end{aligned}
$$

Since there exists some $j$ such that $\phi_{j}>0$, we have

$$
\begin{equation*}
\left\|(A-\alpha I) \hat{s}^{(j)}\right\|=0 \tag{3.32}
\end{equation*}
$$

On the other hand, we get

$$
\begin{align*}
\frac{\left\|\left(A-\alpha_{k} I\right) s_{k}\right\|}{\left\|s_{k}\right\|} & =\frac{\left\|\left(A-\alpha_{k} I\right) A^{-r_{j} / 2} A^{r_{j} / 2} s_{k}\right\|}{\left\|s_{k}\right\|} \\
& \leq \frac{\left\|A^{-r_{j} / 2}\right\|\left\|\left(A-\alpha_{k} I\right) A^{r_{j} / 2} s_{k}\right\|\left\|A^{r_{j} / 2} s_{k}\right\|}{\left\|A^{r_{j} / 2} s_{k}\right\|} \\
& \leq \frac{\left\|A^{-r_{j} / 2}\right\|\left\|\left(A-\alpha_{k} I\right) A^{r_{j} / 2} s_{k}\right\|}{\left\|s_{k}\right\|} \frac{\left\|A^{r_{j} / 2}\right\|\left\|s_{k}\right\|}{\| s_{k} / 2} s_{k} \| \\
& =\left\|A^{r_{j} / 2}\right\|\left\|A^{-r_{j} / 2}\right\| \frac{\left\|\left(A-\alpha_{k} I\right) A^{r_{j} / 2} s_{k}\right\|}{\left\|A^{r_{j} / 2} s_{k}\right\|} . \tag{3.33}
\end{align*}
$$

Therefore, using (3.33) and (3.32), we obtain

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{\left\|\left(A-\alpha_{k} I\right) s_{k}\right\|}{\left\|s_{k}\right\|}=0 \tag{3.34}
\end{equation*}
$$

Because we can regard $\alpha_{k} I$ as $B_{k}$ in Lemma 3, the sequence $\left\{x_{k}\right\}$ converges Q-superlinearly to $x_{*}$. In addition, (3.34) yields

$$
(A-\alpha I) s=0
$$

This means that $s$ is an eigenvector of $A$ with the eigenvalue $\alpha=s^{T} A s$. Therefore, the proof is complete.

Note that Theorem 2 is the extension of Theorem 3.1 in Friedlander et al. [9].

## 4 Extended Barzilai-Borwein method for general functions

In this section, we consider an application of Algorithm EBB to general unconstrained minimization problems (1.1). In (2.1), we use the positive definite matrix $A$ which is the Hessian of the objective function. On the other hand, calculations of the Hessian of the objective function are very expensive if the objective function is not quadratic. Accordingly, we would like to express (3.26) without using the Hessian A. To this end, we fix $r_{i}=0$ or 1 in (3.26) and give

$$
\begin{aligned}
\alpha_{k} & =\sum_{i=1}^{\ell^{\prime}} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} A^{r_{i}+1} s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} A^{r_{i}} s_{\nu_{i}(k)}} \\
& =\sum_{\substack{i=1 \\
r_{i}=0}}^{\ell_{i}} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} A s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} s_{\nu_{i}(k)}}+\sum_{\substack{i=1 \\
r_{i}=1}}^{\ell_{i}^{\prime}} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} A^{2} s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} A s_{\nu_{i}(k)}} \\
& =\sum_{\substack{i=1 \\
r_{i}=0}}^{\ell^{\prime}} \phi_{i} \frac{s_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} s_{\nu_{i}(k)}}+\sum_{\substack{i=1 \\
\ell^{\prime}}} \phi_{i} \frac{y_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}} .
\end{aligned}
$$

Hence we rewrite the above $\alpha_{k}$ and define

$$
\begin{align*}
\alpha_{k} & =\sum_{i=1}^{\ell}\left(\phi_{i}^{(1)} \frac{s_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} s_{\nu_{i}(k)}}+\phi_{i}^{(2)} \frac{y_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} y_{\nu_{i}(k)}}\right)  \tag{4.1}\\
\phi_{i}^{(1)} & \geq 0, \quad \phi_{i}^{(2)} \geq 0, \quad \sum_{i=1}^{\ell}\left(\phi_{i}^{(1)}+\phi_{i}^{(2)}\right)=1,  \tag{4.2}\\
\nu_{i}(k) & \in\{k-1, \ldots, \max \{0, k-m\}\},
\end{align*}
$$

where $\ell$ and $m$ are positive integers, and $q_{1}, \ldots, q_{m}$ are integers. Since (4.1) does not explicitly use the matrix $A$, it can be applied to general objective functions.

For general unconstrained minimization problems, we should use globalization technique. Recently, several researchers pay attention to an application of the nonmonotone
line search, which was originally developed by Grippo et al. [10, 11] for Newton type methods, to gradient-based methods. For example, Dai [2] showed the global convergence of the nonmonotone conjugate gradient method, and Raydan [17] proved the global convergence of the nonmonotone Barzilai-Borwein method. Moreover, Grippo and Sciandrone [12] proposed another type of the nonmonotone Barzilai-Borwein method. Dai [3] gives the basic analysis of the nonmonotone line search strategy.

In this section, following Raydan [17], we combine the nonmonotone line search and Algorithm EBB. The proposed algorithm is given by the following:

Algorithm 2 (Algorithm NEBB)
Step 0. Given $x_{0} \in \boldsymbol{R}^{n}$. Set $k=0,0<\bar{\alpha} \ll 1, \delta>0,0<\eta_{1} \leq \eta_{2}, 0<\eta_{3} \leq \eta_{4}<1$ and $\xi \in(0,1)$, and let $\bar{M}$ be a positive integer. Go to Step 1 .
Step 1. Compute $\alpha_{k}$ by (4.1). If $\bar{\alpha} \leq \alpha_{k} \leq \frac{1}{\bar{\alpha}}$, set $p_{k}=-\frac{1}{\alpha_{k}} g_{k}$, and otherwise set $p_{k}=-\delta g_{k}$.
Step 2. Given $t_{k}^{(0)} \in\left[\eta_{1}, \eta_{2}\right]$ and $M(k)$ such that $M(0)=0$ and $0 \leq M(k) \leq \min \{M(k-$ 1) $+1, \bar{M}\}$ if $k \geq 1$. Set $i=0$ and go to Step 2.1.

Step 2.1. If

$$
\begin{equation*}
f\left(x_{k}+t_{k}^{(i)} p_{k}\right) \leq \max _{0 \leq j \leq M(k)}\left\{f_{k-j}\right\}+\xi t_{k}^{(i)} g_{k}^{T} p_{k} \tag{4.3}
\end{equation*}
$$

holds, set $t_{k} \equiv t_{k}^{(i)}$ and go to Step 3.
Step 2.2. Choose $\sigma_{k}^{(i)} \in\left[\eta_{3}, \eta_{4}\right]$ and compute $t_{k}^{(i+1)}$ such that

$$
\begin{equation*}
t_{k}^{(i+1)}=t_{k}^{(i)} \sigma_{k}^{(i)} \tag{4.4}
\end{equation*}
$$

Step 2.3 . Set $i:=i+1$ and go to Step 2.1.
Step 3. Let $x_{k+1}=x_{k}+t_{k} p_{k}$. If the stopping criterion is satisfied, then stop.
Step 4. Let $k:=k+1$ and go to Step 1.
In Step 2, usually we choose $t_{k}^{(0)}=1$. Since we choose a small value as $\bar{\alpha}, p_{k}=-\frac{1}{\alpha_{k}} g_{k}$ would be chosen in almost all iterations as far as $\alpha_{k}>0$. We note that the search direction $p_{k}$ satisfies

$$
\begin{equation*}
g_{k}^{T} p_{k} \leq-c_{1}\left\|g_{k}\right\|^{2} \quad \text { and } \quad\left\|p_{k}\right\| \leq c_{2}\left\|g_{k}\right\| \quad \text { for all } k \tag{4.5}
\end{equation*}
$$

for some positive constants $c_{1}$ and $c_{2}$. These relations lead to the following theorem.
Theorem 3 Assume that the objective function $f$ is bounded below on $\boldsymbol{R}^{n}$ and is continuously differentiable in a neighborhood $\mathcal{N}$ of the level set $\mathcal{L}=\left\{x \in \boldsymbol{R}^{n}: f(x) \leq f\left(x_{0}\right)\right\}$. We also assume that the gradient $g$ is Lipschitz continuous in $\mathcal{N}$. Let the sequence $\left\{x_{k}\right\}$ be generated by Algorithm NEBB. Then our method converges in the sense that

$$
\lim _{k \rightarrow \infty}\left\|g_{k}\right\|=0
$$

Proof. From (4.5) and Theorem 2.1 of Dai [3], we have the results immediately.

In the rest of this section, we denote $\nabla^{2} f$ by $H$, and $\nabla^{2} f\left(x_{*}\right)$ by $H_{*}$.
Next we consider the local behavior of the extended Barzilai-Borwein method for general functions. For the end, we make the following assumptions.

## Assumption 1

1. The objective function $f$ is twice continuously differentiable in an open convex neighborhood $\mathcal{N}$ of the local solution $x_{*}$. In addition, there exist positive constants $m_{1}$ and $m_{2}$ such that

$$
\begin{equation*}
m_{1}\|v\|^{2} \leq v^{T} H(x) v \leq m_{2}\|v\|^{2} \quad \text { for all } x \in \mathcal{N} \text { and } v \in \boldsymbol{R}^{n} \tag{4.6}
\end{equation*}
$$

2. In Step 2 of Algorithm $N E B B, t_{k}=1$ is chosen for $k$ sufficiently large. The parameter $\bar{\alpha}$ satisfies $\bar{\alpha} \leq m_{1}$ and $m_{2} \leq \frac{1}{\bar{\alpha}}$.
3. The sequence $\left\{x_{k}\right\}$ generated by Algorithm NEBB converges to the solution $x_{*}$.

Under Assumption 1, we obtain the following theorem.
Theorem 4 Let $\left\{x_{k}\right\}$ be the sequence generated by Algorithm NEBB. Suppose that Assumption 1 holds, and that the sequence $\left\{s_{k} /\left\|s_{k}\right\|\right\}$ is convergent, that is, there exists $s \in \boldsymbol{R}^{n}$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{s_{k}}{\left\|s_{k}\right\|}=s \quad \text { and } \quad\|s\|=1 \tag{4.7}
\end{equation*}
$$

Then $s$ becomes an eigenvector of $H_{*}$ with the eigenvalue $s^{T} H_{*} s$ and

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \alpha_{k}=s^{T} H_{*} s \tag{4.8}
\end{equation*}
$$

Moreover, the sequence $\left\{x_{k}\right\}$ converges $Q$-superlinearly to $x_{*}$.
Proof. We assume that $k$ is sufficiently large. From Assumption $1, x_{k} \in \mathcal{N}$ for all $k$. By the mean value theorem, we have

$$
y_{k}=\int_{0}^{1} H\left(x_{k}+t s_{k}\right) s_{k} d t .
$$

Since from (4.6) $H(x)$ is symmetric positive definite in $\mathcal{N}, H(x)^{1 / 2}$ is well-defined in $\mathcal{N}$. We define $\tilde{H}_{k} \equiv \int_{0}^{1} H\left(x_{k}+t s_{k}\right) d t$ and $\tilde{s}_{k} \equiv \tilde{H}_{k}^{1 / 2} s_{k}$. Then

$$
\begin{align*}
\alpha_{k} & =\sum_{i=1}^{\ell}\left\{\phi_{i}^{(1)} \frac{s_{\nu_{i}(k)}^{T} \tilde{H}_{\nu_{i}(k)} s_{\nu_{i}(k)}}{s_{\nu_{i}(k)}^{T} s_{\nu_{i}(k)}}+\phi_{i}^{(2)} \frac{\tilde{s}_{\nu_{i}(k)}^{T}}{\tilde{s}_{\nu_{\nu_{i}}(k)}^{T} \tilde{S}_{\nu_{i}(k)}} \tilde{s}_{\nu_{i}(k)}\right. \\
& =\sum_{i=1}^{\ell}\left\{\phi_{i}^{(1)}\left(\frac{s_{\nu_{i}(k)}}{\left\|s_{\nu_{i}(k)}\right\|}\right)^{T} \tilde{H}_{\nu_{i}(k)}\left(\frac{s_{\nu_{i}(k)}}{\left\|s_{\nu_{i}(k)}\right\|}\right)+\phi_{i}^{(2)}\left(\frac{\tilde{s}_{\nu_{i}(k)}}{\left\|\tilde{s}_{\nu_{i}(k)}\right\|}\right)^{T} \tilde{H}_{\nu_{i}(k)}\left(\frac{\tilde{s}_{\nu_{i}(k)}}{\left\|\tilde{s}_{\nu_{i}(k)}\right\|}\right)\right\} . \tag{4.9}
\end{align*}
$$

It follows from the definition of $\tilde{s}_{\nu_{i}(k)}$ that

$$
\lim _{k \rightarrow \infty} \frac{\tilde{s}_{\nu_{i}(k)}}{\left\|\tilde{s}_{\nu_{i}(k)}\right\|}=\lim _{k \rightarrow \infty} \frac{\tilde{H}_{\nu_{i}(k)}^{1 / 2} s_{\nu_{i}(k)} /\left\|s_{\nu_{i}(k)}\right\|}{\left\|\tilde{H}_{\nu_{i}(k)}^{1 / 2} s_{\nu_{i}(k)}\right\| /\left\|s_{\nu_{i}(k)}\right\|}=\frac{H_{*}^{1 / 2} s}{\left\|H_{*}^{1 / 2} s\right\|} .
$$

Therefore, by taking limit, we obtain

$$
\begin{equation*}
\alpha \equiv \lim _{k \rightarrow \infty} \alpha_{k}=\sum_{i=1}^{\ell}\left(\phi_{i}^{(1)} s^{T} H_{*} s+\phi_{i}^{(2)} \tilde{s}^{T} H_{*} \tilde{s}\right), \tag{4.10}
\end{equation*}
$$

where $\tilde{s} \equiv H_{*}^{1 / 2} s /\left\|H_{*}^{1 / 2} s\right\|$. On the other hand, (4.6) and (4.9) yield $m_{1} \leq \alpha_{k} \leq m_{2}$. Thus, it follows from the assumptions $\bar{\alpha} \leq m_{1}, m_{2} \leq \frac{1}{\bar{\alpha}}$ and (4.1) that

$$
\begin{equation*}
p_{k}=-\frac{1}{\alpha_{k}} g_{k}, \quad x_{k+1}=x_{k}-\frac{1}{\alpha_{k}} g_{k} \quad \text { and } \quad s_{k}=-\frac{1}{\alpha_{k}} g_{k} \tag{4.11}
\end{equation*}
$$

hold. By using the mean value theorem, we have

$$
\begin{equation*}
g_{k}=g\left(x_{*}\right)+\int_{0}^{1} H\left(x_{*}+t\left(x_{k}-x_{*}\right)\right)\left(x_{k}-x_{*}\right) d t=-\int_{0}^{1} H\left(x_{*}-t e_{k}\right) d t e_{k}, \tag{4.12}
\end{equation*}
$$

where $e_{k}=x_{*}-x_{k}$. Set $\hat{H}_{k} \equiv \int_{0}^{1} H\left(x_{*}-t e_{k}\right) d t$. Since (4.11) and (4.12) yield

$$
\begin{equation*}
s_{k}=-\frac{1}{\alpha_{k}} g_{k}=\frac{1}{\alpha_{k}} \hat{H}_{k} e_{k} \tag{4.13}
\end{equation*}
$$

and

$$
\begin{equation*}
e_{k+1}=e_{k}-s_{k}=e_{k}-\frac{1}{\alpha_{k}} \hat{H}_{k} e_{k}=\left(I-\frac{1}{\alpha_{k}} \hat{H}_{k}\right) e_{k} . \tag{4.14}
\end{equation*}
$$

Since $e_{k}=\alpha_{k} \hat{H}_{k}^{-1} s_{k}$, we have from (4.13) and (4.14)

$$
\begin{align*}
s_{k+1} & =\frac{1}{\alpha_{k+1}} \hat{H}_{k+1} e_{k+1} \\
& =\frac{1}{\alpha_{k+1}} \hat{H}_{k+1}\left(I-\frac{1}{\alpha_{k}} \hat{H}_{k}\right) e_{k} \\
& =\frac{1}{\alpha_{k+1}} \hat{H}_{k+1}\left(I-\frac{1}{\alpha_{k}} \hat{H}_{k}\right) \alpha_{k} \hat{H}_{k}^{-1} s_{k} \\
& =-\frac{1}{\alpha_{k+1}} \hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) s_{k} . \tag{4.15}
\end{align*}
$$

We normalize the above equation, and we get

$$
\frac{s_{k+1}}{\left\|s_{k+1}\right\|}=-\frac{\hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) s_{k}}{\left\|\hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) s_{k}\right\|}
$$

which implies

$$
\left\|\hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) \frac{s_{k}}{\left\|s_{k}\right\|}\right\| \frac{s_{k+1}}{\left\|s_{k+1}\right\|}=-\hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) \frac{s_{k}}{\left\|s_{k}\right\|}
$$

Taking limits on both sides of this equation, we have

$$
\left\|\left(H_{*}-\alpha I\right) s\right\| s=-\left(H_{*}-\alpha I\right) s
$$

and hence, premultiplying this equation by $s^{T}$, we have from $\|s\|=1$

$$
\begin{equation*}
\left\|\left(H_{*}-\alpha I\right) s\right\|=-s^{T} H_{*} s+\alpha . \tag{4.16}
\end{equation*}
$$

Moreover, since (4.15) yields $H_{*}^{1 / 2} s_{k+1}=-\frac{1}{\alpha_{k+1}} H_{*}^{1 / 2} \hat{H}_{k+1} \hat{H}_{k}^{-1}\left(\hat{H}_{k}-\alpha_{k} I\right) s_{k}$, we also have, in a similar way,

$$
\begin{equation*}
\left\|\left(H_{*}-\alpha I\right) \tilde{s}\right\|=-\tilde{s}^{T} H_{*} \tilde{s}+\alpha . \tag{4.17}
\end{equation*}
$$

Therefore, from (4.10), (4.16) and (4.17), we get

$$
\begin{aligned}
\sum_{i=1}^{\ell}\left(\phi_{i}^{(1)}\left\|\left(H_{*}-\alpha I\right) s\right\|+\phi_{i}^{(2)}\left\|\left(H_{*}-\alpha I\right) \tilde{s}\right\|\right) & =-\sum_{i=1}^{\ell}\left(\phi_{i}^{(1)} s^{T} H_{*} s+\phi_{i}^{(2)} \tilde{s}^{T} H_{*} \tilde{s}\right)+\alpha \\
& =0,
\end{aligned}
$$

which implies that either $\left\|\left(H_{*}-\alpha I\right) s\right\|=0$ or $\left\|\left(H_{*}-\alpha I\right) \tilde{s}\right\|=0$ holds. Since conditions $\left\|\left(H_{*}-\alpha I\right) s\right\|=0$ and $\left\|\left(H_{*}-\alpha I\right) \tilde{s}\right\|=0$ are equivalent, we consider only the case $\left\|\left(H_{*}-\alpha I\right) s\right\|=0$. Thus we have

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \frac{\left\|\left(H_{*}-\alpha_{k} I\right) s_{k}\right\|}{\left\|s_{k}\right\|}=\left\|\left(H_{*}-\alpha I\right) s\right\|=0 . \tag{4.18}
\end{equation*}
$$

Because we can regard $\alpha_{k} I$ as $B_{k}$ in Lemma 3, the sequence $\left\{x_{k}\right\}$ converges Q-superlinearly to $x_{*}$. In addition, (4.18) yields

$$
\left(H_{*}-\alpha I\right) s=0
$$

This means that $s$ is an eigenvector of $H_{*}$ with the eigenvalue $\alpha=s^{T} H_{*} s$. Therefore, the proof is complete.

## 5 Numerical experiments

In this section, we present some numerical results of Algorithm EBB and NEBB to compare with other methods. Since the steepest descent method converged very slowly, we omit its numerical result. Moreover, we investigate how a choice of the parameters included in our methods affects numerical performance.

In our numerical experiments, we set $\ell=2$ and $r_{1}=r_{2}(=r)$. Moreover, we fix $r=0$ or 1 . Thus $\alpha_{k}$ in (3.26) is rewritten by the forms

- $\quad r=0$

$$
\alpha_{k}=\phi_{1} \frac{s_{\nu_{1}(k)}^{T} y_{\nu_{1}(k)}}{s_{\nu_{1}(k)}^{T} s_{\nu_{1}(k)}}+\phi_{2} \frac{s_{\nu_{2}(k)}^{T} y_{\nu_{2}(k)}}{s_{\nu_{2}(k)}^{T} s_{\nu_{2}(k)}}, \quad \phi_{1}+\phi_{2}=1, \quad \phi_{1} \geq 0, \quad \phi_{2} \geq 0
$$

- $r=1$

$$
\alpha_{k}=\phi_{1} \frac{y_{\nu_{1}(k)}^{T} y_{\nu_{1}(k)}}{s_{\nu_{1}(k)}^{T} y_{\nu_{1}(k)}}+\phi_{2} \frac{y_{\nu_{2}(k)}^{T} y_{\nu_{2}(k)}}{s_{\nu_{2}(k)}^{T} y_{\nu_{2}(k)}}, \quad \phi_{1}+\phi_{2}=1, \quad \phi_{1} \geq 0, \quad \phi_{2} \geq 0 .
$$

As mentioned in Section 2, if we choose $\phi_{1}=1, \phi_{2}=0, r=0$, and $\nu_{1}(k)=k-1$, then it becomes the Barzilai-Borwein method, and if we choose $\phi_{1}=1$ and $\phi_{2}=0$, then it becomes the gradient method with retards.

Following Dai et al. [4], we used the following choice of $\nu_{i}(k)$ :

$$
\begin{equation*}
\nu_{i}(k)=M_{c}\left\lfloor\frac{k-m_{i}}{M_{c}}\right\rfloor, \tag{5.1}
\end{equation*}
$$

where $m_{i}(i=1,2)$ are positive integers. In this section, we call Algorithms EBB and NEBB with (5.1) cyclic $E B B$ and cyclic $N E B B$, respectively. If $\phi_{1}=1, \phi_{2}=0, m_{1}=1$ and $r=0$, we see that

$$
\alpha_{k}=\frac{s_{\nu_{1}(k)}^{T} y_{\nu_{1}(k)}}{s_{\nu_{1}(k)}^{T} s_{\nu_{1}(k)}} \quad \text { and } \quad \nu_{1}(k)=M_{c}\left\lfloor\frac{k-1}{M_{c}}\right\rfloor
$$

which is the cyclic Barzilai-Borwein method. In each experiment, we set $\alpha_{0}=1$. The parameters used in our experiments are described in each table. Note that the values of parameters $\nu_{i}(k), M_{c}$ and $m_{i}(i=1,2)$ indicate how old information we use. For example, if we choose $\nu_{1}(k)=k-5$ and $\nu_{2}(k)=k-6$, we use $g_{k-5}$ and $g_{k-6}$ at the $k$-th iteration, and if we choose $M_{c}=5, m_{1}=3$ and $m_{2}=4$, we use $g_{k-9}$ according to circumstances.

We used the following stopping condition:

$$
\left\|g_{k}\right\| \leq 10^{-5}
$$

### 5.1 Numerical results of Algorithm EBB for (1.6)

In this subsection, we give some numerical results of Algorithm EBB. The objective function we used is

$$
f(x)=\frac{1}{2} x^{T} A x, \quad x \in \boldsymbol{R}^{n} .
$$

The following matrices are chosen as the matrix $A$ :

- Diag: the diagonal matrix defined by

$$
\operatorname{diag}\left\{1, \frac{\lambda_{n}}{n} 2, \ldots, \frac{\lambda_{n}}{n} i, \ldots, \lambda_{n}\right\}
$$

- Hilbert: the Hilbert matrix.
- bcsstm: symmetric positive definite matrices in Matrix Market [13].

We set $x_{0}=(1, \ldots, 1)^{T}$ as a starting point.
The numerical results of Algorithm EBB are reported in Tables 2-4. We give the number of iterations in each table, and "Sum " in each column denotes the sum of the number of iterations. In addition, " Failed " means that the number of iterations exceeds 10000. In each column, if there are "Failed", then we wrote" $*$ " in "Sum ".

From Table 2, we see the following observations.

- By comparing each "Sum", the method with $\left(r, \phi_{1}, \phi_{2}, \nu_{1}(k), \nu_{2}(k)\right)=(1,1,0, k-$ $3,-)$ performed well. In addition, the methods with $\left(r, \phi_{1}, \phi_{2}, \nu_{1}(k), \nu_{2}(k)\right)=(0,1,0, k-$ $3,-),(1,0.25,0.75, k-3, k-4),(1,0.75,0.25, k-3, k-4)$ also performed well.
- For the cases $\nu_{1}(k)=k-1$ and $\nu_{2}(k)=k-2$, our methods did not converge to the solution occasionally.
- Choices of $\nu_{1}(k), \nu_{2}(k)$ and $r$ affected the numerical results more than choices of $\phi_{1}$ and $\phi_{2}$ did.

From Tables 3 and 4, we see the following observations.

- The cyclic EBB with $M_{c}=3$ is supreior to the cyclic EBB with $M_{c}=5$.
- In Table 3, the cyclic EBB with $\left(M_{c}, m_{1}, m_{2}\right)=(3,3,4)$ and $(3,3,-)$ (which means $\phi_{1}, \phi_{2}$ and $r$ are any parameters) performed better than other methods.
- For the cases $\left(M_{c}, m_{1}, m_{2}\right)=(3,1,2)$, our methods did not converge to the solution occasionally.

Summarizing our numerical results, we conclude that the numerical performance of our method was greatly affected by the choice of $\nu_{i}(k)$ (or $M_{c}$ and $m_{i}$ ). Taking into account that the steepest descent method is involved in the case $\nu_{1}(k)=k$ (it means current information), we see that our method with old information performed better than that with current or near current information. However, if we use too old information, then our method becomes unstable. It is important to find proper choices of $\nu_{i}(k)$ (or $M_{c}$ and $\left.m_{i}\right)$. In our numerical results, EBB with $\left(\nu_{1}(k), \nu_{2}(k)\right)=(3,4)$, and the cyclic EBB with $\left(M_{c}, m_{1}, m_{2}\right)=(3,3,4)$ performed well. On the other hand, the choices of the other parameters also affected the numerical performance of our method, but we cannot observe any remarkable tendency.

### 5.2 Numerical results of Algorithm NEBB for (1.1)

In this subsection, we give some numerical results of Algorithm NEBB. The test problems we used are described in Grippo et al. [11] and Moré et al. [14]. In Table 1, the first column, the second column, the third column and the fourth column denote the problem number used in this paper, the problem name, the dimension of the problem and the references, respectively.

Table 1. Test problems

| P | Name | Dimension | References |
| :---: | :---: | :---: | :---: |
| 1 | Extended Rosenbrock Function | $\mathrm{n}=10000$ | Moré et al. [14] |
| 2 | Extended Powell Singular Function | $\mathrm{n}=10000$ | Moré et al. [14] |
| 3 | Trigonometric Function | $\mathrm{n}=10000$ | Moré et al. [14] |
| 4 | Broyden Tridiagonal Function | $\mathrm{n}=10000$ | Moré et al. [14] |
| 5 | Oren Function | $\mathrm{n}=100$ | Grippo et al. [11] |
| 6 | Cube Function | $\mathrm{n}=2$ | Grippo et al. [11] |
| 7 | Wood Function | $\mathrm{n}=4$ | Moré et al. [14] |
| 8 | Beale Function | $\mathrm{n}=2$ | Moré et al. [14] |
| 9 | Helical Valley Function | $\mathrm{n}=3$ | Moré et al. [14] |
| 10 | Jennrich and Sampson Function | $\mathrm{n}=2$ | Moré et al. [14] |
| 11 | Freudenstein and Roth Function | $\mathrm{n}=2$ | Moré et al. [14] |

In Algorithm NEBB, we set parameters $\bar{\alpha}=10^{-16}, \delta=1, \xi=0.0001, t_{k}^{(0)}=1$, $\bar{M}=10, \sigma_{k}^{(i)}=0.5$.

The numerical results of Algorithm NEBB are reported in Tables 5-7. The numerical results are given in the form of "the number of iterations / the number of function evaluations", and "Sum I" and "Sum F" denote the sum of the number of iterations and the sum of the number of function evaluations, respectively. We note that the number of gradient evaluations is the same as the number of iterations. In addition, " Failed " means that the number of iterations exceeds 1000 .

In order to compare our method with conjugate gradient (CG) methods, we examined typical CG methods (Fletcher-Reeves (FR) method, Hestenes-Stiefel (HS) method, PolakRibière Plus (PR+) method, and Dai-Yuan (DY) method, see [15] for example). In the line search procedure, we used the Armijo condition and the bisection method, which means Step 2 of Algorithm NEBB with $\xi=0.1, M(k)=0, t_{k}^{(0)}=1$ and $\sigma_{k}^{(i)}=0.5$. In each iteration, if CG methods did not generate a descent direction, then we used the steepest descent direction. However such a case rarely occurred. The CG methods, for Problems 4 and 5, did not converge to the solution. So we omit these numerical results. The numerical results of CG methods are given in Table 8.

For Algorithm NEBB, we investigate the frequency of taking $t_{k}=1$, namely $x_{k+1}=$ $x_{k}-\frac{1}{\alpha_{k}} g_{k}$. The frequency of taking $t_{k}=1$ depended on problems and the choice of parameters. The ratio (the frequency of taking $t_{k}=1$ /the number of iterations) are $65 \%$ $-100 \%$. In Tables $5-7$, the averages of the ratio are $85 \%, 82 \%$ and $79 \%$, respectively. It
seems that the older information becomes, the lower the ratio becomes.
From Tables 5-7, we see the following observations.

- NEBB with $\left(r, \phi_{1}, \phi_{2}, \nu_{1}(k), \nu_{2}(k)\right)=(1,0.5,0.5, k-1, k-2)$ and $(1,0.25,0.75, k-$ $1, k-2)$ performed better than the other variants.
- NEBB with $\left(\nu_{1}(k), \nu_{2}(k)\right)=(k-1, k-2)$ needed the number of function evaluations less than NEBB with $\left(\nu_{1}(k), \nu_{2}(k)\right)=(k-3, k-4)$.
- The cyclic NEBB with $\left(r, M_{c}, m_{1}, m_{2}\right)=(0,3,1,2),(0,5,3,-)$ and $(0,5,3,4)$ did not converge to the solution for P2.

Summarizing our numerical results, we conclude that the numerical performance of our method was greatly affected by not only the choice of $\nu_{i}(k)$ (or $M_{c}$ and $m_{i}$ ) but also $r$. Especially, we find that the choice $r=1$ is more appropriate than the choice $r=0$ for general objective functions. It seems that the older information becomes, the more the number of function evaluations we need. We recommend NEBB with $\left(r, M_{c}, \phi_{1}, \phi_{2}, m_{1}, m_{2}\right)=$ $(1,0.5,0.5, k-1, k-2)$ and $(1,0.25,0.75, k-1, k-2)$. By comparing NEBB (with $\left(r, M_{c}, \phi_{1}, \phi_{2}, m_{1}, m_{2}\right)=(1,0.5,0.5, k-1, k-2)$ and $\left.(1,0.25,0.75, k-1, k-2)\right)$ with conjugate gradient methods, NEBB needed the number of iterations more than conjugate gradient methods, while NEBB is superior to conjugate gradient methods from the viewpoint of the number of function evaluations. When the number of variables is very large, the computational effort is sometimes dominated by the cost of evaluating the function and the cost of evaluating the gradient. Therefore we can regard our methods as efficient methods for large scale problems.

## 6 Concluding remarks

In this paper, we have proposed the extended Barzilai-Borwein method which includes the steepest descent method, the Barzilai-Borwein method and the gradient method with retards. We have established the global and Q-superlinear convergence properties of the proposed method. Moreover, numerical performance of our method has been investigated by some numerical experiments. Our further interests are to find a suitable choice of parameters included in our method.
