

# NONSMOOTH ALGORITHMS AND NESTEROV'S SMOOTHING TECHNIQUE FOR GENERALIZED FERMAT-TORRICELLI PROBLEMS

Nguyen Mau Nam<sup>1</sup>, Nguyen Thai An<sup>2</sup>, R. Blake Rector<sup>3</sup>, Jie Sun<sup>4</sup>.

**Abstract:** We present some algorithms for solving a number of new models of facility location which generalize the classical Fermat-Torricelli problem. Our first approach involves using the MM Principle and Nesterov's smoothing technique to build smooth approximations that are convenient for applying smooth optimization schemes. Another approach uses subgradient-type algorithms to cope directly with the nondifferentiability of the cost functions. Convergence results of the algorithms are proved and numerical tests are presented to show the effectiveness of the proposed algorithms.

**Key words.** MM Principle, Nesterov's smoothing technique, Nesterov's accelerated gradient method, generalized Fermat-Torricelli problem, subgradient-type algorithms.

**AMS subject classification.** 49J52, 49K40, 58C20

## 1 Introduction

The *Fermat-Torricelli problem* was introduced in the 17th century by the French mathematician Pierre de Fermat and can be stated as follows: Given a finite collection of points in the plane, find a point that minimizes the sum of the distances to those points. This practical problem has been the inspiration for many new problems in the fields of computational geometry, logistics and location science. Many generalized versions of the Fermat-Torricelli have been introduced and studied over the years; see [13, 14, 16, 18–20, 25] and the references therein. In particular, the generalized Fermat-Torricelli problems involving distances to sets were the topics of a recent study; see [2, 4, 7, 18, 19].

In this paper, we focus mainly on developing effective numerical algorithms for generalized Fermat-Torricelli problems. Let  $\mathbb{R}^n$  be the  $n$ -dimensional Euclidean space. Given a nonempty closed bounded convex set  $F \subset \mathbb{R}^n$  that contains the origin as an interior point, define the function

$$(1) \quad \sigma_F(u) := \sup\{\langle u, x \rangle \mid x \in F\},$$

which reduces to the *dual norm* generated by a norm  $\|\cdot\|_X$  when  $F := \{x \in \mathbb{R}^n \mid \|x\|_X \leq 1\}$ .

The *generalized distance function* defined by the *dynamic*  $F$  and the *target set*  $\Omega$  is given by

$$(2) \quad d_F(x; \Omega) := \inf\{\sigma_F(x - w) \mid w \in \Omega\}.$$

If  $F$  is the closed unit Euclidean ball of  $\mathbb{R}^n$ , the function (2) reduces to the *shortest distance function* or simply *distance function*

$$(3) \quad d(x; \Omega) := \inf\{\|x - w\| \mid w \in \Omega\}.$$

Given a finite collection of nonempty closed convex sets  $\Omega_i$  for  $i = 1, \dots, m$ , consider the following optimization problem:

$$(4) \quad \text{minimize } T(x), \quad x \in \Omega,$$

where  $\Omega$  is a convex constraint set, and the cost function  $T$  is defined by

$$T(x) := \sum_{i=1}^m d_F(x; \Omega_i).$$

If  $F$  is the closed unit Euclidean ball of  $\mathbb{R}^n$ , problem (4) reduces to a simpler version as below:

$$\text{minimize } \mathcal{D}(x) := \sum_{i=1}^m d(x; \Omega_i), \quad x \in \Omega.$$

In the general case of problem (4), the objective function  $T$  is not necessarily smooth. To solve problem (4) or, more generally, a nonsmooth optimization problem, a natural idea involves using smoothing techniques to approximate the original nonsmooth problem by a smooth one. Then, different smooth optimization schemes are applied to the smooth problem. One of the successful implementations of this idea was provided by Nesterov. In his seminal papers [22, 24], Nesterov introduced a fast first-order method for solving convex smooth optimization problems in which the cost functions have Lipschitz gradient. In contrast to the convergence rate of  $O(1/k)$  when applying the classical gradient method to this class of problems, Nesterov's accelerated gradient method gives a convergence rate of  $O(1/k^2)$ . In Nesterov's nonsmooth optimization scheme, an original nonsmooth function of a particular form is approximated by a smooth convex function with Lipschitz gradient. Then the accelerated gradient method can be applied to solve the smooth approximation.

Another approach uses subgradient-type algorithms to cope directly with the nondifferentiability. In fact, subgradient-type algorithms allow us to solve the problem in very broad settings that involve distance functions generated by different norms and also generalized distance functions generated by different dynamics. However, the classical subgradient method is known to be slow in general. Thus, it is not a good option when the number of target sets is large in high dimensions. We apply the *stochastic subgradient method* to deal with this situation. It has been shown that the stochastic subgradient method is an effective tool for solving many practical problems; see [1, 28] and the references therein. This simple method also shows its effectiveness for solving the generalized Fermat-Torricelli problem.

The remainder of this paper is organized as follows. In Section 2 we give an introduction to Nesterov’s smoothing technique, Nesterov’s accelerated gradient method, and the MM Principle to solve nonsmooth optimization problems. These tools will be used in Sections 3 and 4 to develop numerical algorithms for solving generalized Fermat-Torricelli problems with points and sets. Subgradient-type algorithms for solving these problems are presented in Section 4. Section 5 contains numerical examples to illustrate the algorithms.

Throughout the paper,  $\langle \cdot, \cdot \rangle$  denotes the usual inner product in  $\mathbb{R}^n$ , and the corresponding Euclidean norm is denoted by  $\|\cdot\|$ ;  $F$  is assumed to be a nonempty closed convex set in  $\mathbb{R}^n$  that contains 0 as an interior point;  $\text{bd } F$  denotes the topological boundary of  $F$ ;  $\Omega$  and  $\Omega_i$  for  $i = 1, \dots, m$  are nonempty closed convex subsets of  $\mathbb{R}^n$ . We also use basic concepts and results of convex optimization, which can be found, e.g., in [23, 26].

## 2 Nesterov’s Smoothing Technique, Accelerated Gradient Method, and MM Principle

In this section we study and provide more details on Nesterov’s smoothing technique and accelerated gradient method introduced in [22]. We also present a general form of the MM Principle well known in computational statistics.

Let  $f: \mathbb{R}^n \rightarrow \mathbb{R}$  be a convex function. Consider the constrained optimization problem

$$\text{minimize } f(x), \quad x \in \Omega,$$

where  $f$  is not necessarily differentiable and  $\Omega$  is a nonempty closed convex subset of  $\mathbb{R}^n$ .

The class of functions we are interested in is given by

$$f(x) := \max\{\langle Ax, u \rangle - \phi(u) \mid u \in Q\}, \quad x \in \mathbb{R}^n,$$

where  $A$  is an  $m \times n$  matrix,  $Q$  is a nonempty closed convex subset of  $\mathbb{R}^m$ , and  $\phi$  is a continuous convex function on  $Q$ .

Let  $d$  be a continuous *strongly convex function* on  $Q$  with parameter  $\sigma > 0$ . The function  $d$  is called a *prox-function*. Since  $d$  is strongly convex on  $Q$ , it has a unique optimal solution on this set. Denote

$$\bar{u} := \arg \min\{d(u) \mid u \in Q\}.$$

Without loss of generality, we assume that  $d(\bar{u}) = 0$ . From the strong convexity of  $d$ , we also have

$$d(u) \geq \frac{\sigma}{2} \|u - \bar{u}\|^2 \text{ for all } u \in Q.$$

Throughout the paper we will work mainly with the case where  $d(u) = \frac{1}{2} \|u - \bar{u}\|^2$ .

Let  $\mu$  be a positive number called a *smooth parameter*. Define

$$(5) \quad f_\mu(x) := \max\{\langle Ax, u \rangle - \phi(u) - \mu d(u) \mid u \in Q\}.$$

The function  $f_\mu$  will be the smooth approximation of  $f$ .

For an  $m \times n$  matrix  $A = (a_{ij})$ , define

$$(6) \quad \|A\| := \max\{\|Ax\| \mid \|x\| \leq 1\}.$$

The definition gives us

$$\|Ax\| \leq \|A\| \|x\| \text{ for all } x \in \mathbb{R}^n.$$

We also recall the definition of the *Euclidean projection* from point  $x \in \mathbb{R}^n$  to a nonempty closed convex subset  $\Omega$  of  $\mathbb{R}^n$ :

$$\Pi(x; \Omega) := \{w \in \Omega \mid d(x; \Omega) = \|x - w\|\}.$$

Let us present below a simplified version of [22, Theorem 1] that involves the usual inner product and the Euclidean norm of  $\mathbb{R}^n$ .

**Theorem 2.1** *The function  $f_\mu$  in (5) is well defined and continuously differentiable on  $\mathbb{R}^n$ . The gradient of the function is*

$$\nabla f_\mu(x) = A^T u_\mu(x),$$

where  $u_\mu(x)$  is the unique element of  $Q$  such that the maximum is attained in (5). Moreover,  $\nabla f_\mu$  is a Lipschitz function with Lipschitz constant

$$\ell_\mu = \frac{1}{\mu\sigma} \|A\|^2.$$

Let  $D := \max\{d(u) \mid u \in Q\}$ . Then

$$f_\mu(x) \leq f(x) \leq f_\mu(x) + \mu D \text{ for all } x \in \mathbb{R}^n.$$

Obtaining the gradient of the function  $f_\mu$  and its Lipschitz constant is the most crucial when implementing Nesterov's accelerated gradient method for minimizing the function  $f_\mu$ . In what follows, let us consider a smaller class of functions for which the gradient of  $f_\mu$  has an explicit representation.

**Proposition 2.2** *Consider the function  $f$  given by*

$$f(x) := \max\{\langle Ax, u \rangle - \langle b, u \rangle \mid u \in Q\}, \quad x \in \mathbb{R}^n,$$

where  $A$  is an  $m \times n$  matrix and  $Q$  is a compact subset of  $\mathbb{R}^m$ . Let  $d(u) = \frac{1}{2} \|u - \bar{u}\|^2$  with  $\bar{u} \in Q$ .

Then the conclusions of Theorem 2.1 hold true with

$$\nabla f_\mu(x) = A^T u_\mu(x),$$

where  $u_\mu$  can be expressed in terms of the Euclidean projection

$$u_\mu(x) = \Pi\left(\bar{u} + \frac{Ax - b}{\mu}; Q\right).$$

The function  $f_\mu$  has the explicit representation

$$f_\mu(x) = \frac{\|Ax - b\|^2}{2\mu} + \langle Ax - b, \bar{u} \rangle - \frac{\mu}{2} \left[ d\left(\bar{u} + \frac{Ax - b}{\mu}; Q\right) \right]^2.$$

The gradient  $\nabla f_\mu$  is a Lipschitz function with constant

$$\ell_\mu = \frac{1}{\mu} \|A\|^2.$$

Moreover,

$$f_\mu(x) \leq f(x) \leq f_\mu(x) + \frac{\mu}{2} [D(\bar{u}; Q)]^2 \text{ for all } x \in \mathbb{R}^n,$$

where  $D(\bar{u}; Q)$  is the farthest distance from  $\bar{u}$  to  $Q$  defined by

$$D(\bar{u}; Q) := \sup\{\|\bar{u} - x\| \mid x \in Q\}.$$

**Proof.** Define

$$\varphi_\mu(x, u) := \langle Ax - b, u \rangle - \frac{\mu}{2} \|u - \bar{u}\|^2.$$

Then

$$\begin{aligned} \varphi_\mu(x, u) &= \langle Ax - b, u \rangle - \frac{\mu}{2} \|u - \bar{u}\|^2 \\ &= -\frac{\mu}{2} (\|u - \bar{u}\|^2 - \frac{2}{\mu} \langle Ax - b, u \rangle) \\ &= -\frac{\mu}{2} (\|u - \bar{u}\|^2 - \frac{2}{\mu} \langle Ax - b, u - \bar{u} \rangle - \frac{2}{\mu} \langle Ax - b, \bar{u} \rangle) \\ &= -\frac{\mu}{2} (\|u - \bar{u} - \frac{Ax - b}{\mu}\|^2 - \frac{\|Ax - b\|^2}{\mu^2} - \frac{2}{\mu} \langle Ax - b, \bar{u} \rangle). \end{aligned}$$

Because

$$f_\mu(x) = \max\{\varphi_\mu(x, u) \mid u \in Q\},$$

the element  $u_\mu(x)$  is the Euclidean projection of  $\bar{u} + \frac{Ax - b}{\mu}$  to the set  $Q$ . The formula for computing  $f_\mu$  is now straightforward.

With this choice of the prox-function  $d$ , the parameter of strong convexity is  $\sigma = 1$ , the constant  $D$  in Theorem 2.1 is given by

$$D = \max\{d(u) \mid u \in Q\} = \max\{\frac{1}{2} \|u - \bar{u}\|^2 \mid u \in Q\} = \frac{1}{2} [D(\bar{u}; Q)]^2.$$

The proof is now complete.  $\square$

**Example 2.3** Let  $\|\cdot\|_{X_1}$  and  $\|\cdot\|_{X_2}$  be two norms in  $\mathbb{R}^m$  and  $\mathbb{R}^n$ , respectively, and let  $\|\cdot\|_{X_1^*}$  and  $\|\cdot\|_{X_2^*}$  be the corresponding dual norms, i.e.,

$$\|u\|_{X_i^*} := \sup\{\langle u, x \rangle \mid \|x\|_{X_i} \leq 1\}, \quad u \in \mathbb{R}^n, \quad i = 1, 2.$$

Denote  $\mathbb{B}_{X_i} := \{x \in \mathbb{R}^n \mid \|x\|_{X_i} \leq 1\}$  for  $i = 1, 2$ . Consider the function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  defined by

$$f(x) := \|Ax - b\|_{X_1^*} + \lambda \|x\|_{X_2^*},$$

where  $A$  is an  $m \times n$  matrix,  $b \in \mathbb{R}^m$ , and  $\lambda > 0$ . Using the prox-function  $d(u) = \frac{1}{2} \|u\|^2$ , one finds a smooth approximation of  $f$  below:

$$f_\mu(x) = \frac{\|Ax - b\|^2}{2\mu} - \frac{\mu}{2} [d(\frac{Ax - b}{\mu}; \mathbb{B}_{X_1})]^2 + \lambda (\frac{\|x\|^2}{2\mu} - \frac{\mu}{2} [d(\frac{x}{\mu}; \mathbb{B}_{X_2})]^2).$$

The gradient of  $f_\mu$  is

$$\nabla f_\mu(x) = A^T \Pi\left(\frac{Ax - b}{\mu}; \mathbb{B}_{X_1}\right) + \lambda \Pi\left(\frac{x}{\mu}; \mathbb{B}_{X_2}\right),$$

and its Lipschitz constant is

$$L_\mu = \frac{\|A\|^2 + \lambda}{\mu}.$$

Moreover,

$$f_\mu(x) \leq f(x) \leq f_\mu(x) + \frac{\mu}{2}([D(0; \mathbb{B}_{X_1})]^2 + [D(0; \mathbb{B}_{X_2})]^2) \text{ for all } x \in \mathbb{R}^n.$$

For example, if  $\|\cdot\|_{X_1}$  is the Euclidean norm, and  $\|\cdot\|_{X_2}$  is the  $\ell^\infty$ -norm on  $\mathbb{R}^n$ , then

$$\nabla f_\mu(x) = A^T \frac{Ax - b}{\max\{\|Ax - b\|, \mu\}} + \lambda \text{median}\left(\frac{x}{\mu}, e, -e\right),$$

where  $e = [1, \dots, 1]^T \in \mathbb{R}^n$ .

Let us provide another example on *support vector machine problems*. Our approach simplifies and improves the results in [29].

**Example 2.4** Let  $S := \{(X_i, y_i)\}_{i=1}^m$  be a training set, where  $X_i \in \mathbb{R}^p$  is the  $i$ th row of a matrix  $X$  and  $y_i \in \{-1, 1\}$ . The corresponding linear support vector machine problem can be reduced to solving the following problem:

$$\text{minimize } g(w) := \frac{1}{2}\|w\|^2 + \lambda \sum_{i=1}^m \ell_i(w), w \in \mathbb{R}^p,$$

where  $\ell_i(w) = \max\{0, 1 - y_i X_i w\}$ ,  $\lambda > 0$ .

Let  $Q := \{u \in \mathbb{R}^m \mid 0 \leq u_i \leq 1\}$  and define

$$f(w) := \sum_{i=1}^m \ell_i(w) = \max_{u \in Q} \langle e - YXw, u \rangle,$$

where  $e = [1, \dots, 1]^T$  and  $Y = \text{diag}(y)$ .

Using the prox-function  $d(u) = \frac{1}{2}\|u\|^2$ , one has

$$f_\mu(w) = \max_{u \in Q} [\langle e - YXw, u \rangle - \mu d(u)].$$

Then

$$u_\mu(w) = \Pi\left(\frac{e - YXw}{\mu}; Q\right) = \{u \in \mathbb{R}^m \mid u_i = \text{median}\left\{\frac{1 - y_i X_i w}{\mu}, 0, 1\right\}\}.$$

The gradient of  $f_\mu$  is given by

$$\nabla f_\mu(w) = -(YX)^T u_\mu(w),$$

and its Lipschitz constant is  $\ell_\mu = \frac{\|YX\|^2}{\mu}$ , where the matrix norm is defined in (6).

Moreover,

$$f_\mu(w) \leq f(w) \leq f_\mu(w) + \frac{m\mu}{2} \text{ for all } w \in \mathbb{R}^p.$$

Then we use the following smooth approximation of the original objective function  $g$ :

$$g_\mu(w) := \frac{1}{2}\|w\|^2 + \lambda f_\mu(w), w \in \mathbb{R}^p.$$

Obviously,

$$\nabla g_\mu(w) = w + \lambda \nabla f_\mu(w),$$

and the Lipschitz constant is

$$L_\mu = 1 + \lambda \frac{\|YX\|^2}{\mu}.$$

The smooth approximations obtained above are convenient for applying Nesterov's accelerated gradient method presented in what follows. Let  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  be a smooth convex function with Lipschitz gradient. That is, there exists  $\ell \geq 0$  such that

$$\|\nabla f(x) - \nabla f(y)\| \leq \ell \|x - y\| \text{ for all } x, y \in \mathbb{R}^n.$$

Let  $\Omega$  be a nonempty closed convex set. In his paper [22], Nesterov considered the optimization problem

$$\text{minimize } f(x) \text{ subject to } x \in \Omega.$$

For  $x \in \mathbb{R}^n$ , define

$$T_\Omega(x) := \arg \min \{ \langle \nabla f(x), y - x \rangle + \frac{\ell}{2} \|x - y\|^2 \mid y \in \Omega \}.$$

Let  $d : \mathbb{R}^n \rightarrow \mathbb{R}$  be a strongly convex function with parameter  $\sigma > 0$ . Let  $x_0 \in \mathbb{R}^n$  such that

$$x_0 = \arg \min \{ d(x) \mid x \in \Omega \}.$$

Further, assume that  $d(x_0) = 0$ . Then Nesterov's accelerated gradient algorithm is outlined as follows.

**Algorithm 1.**

INPUT:  $f, \ell$ .  
INITIALIZE: Choose  $x_0 \in \Omega$ .  
Set  $k = 0$   
**Repeat the following**  
  Find  $y_k := T_\Omega(x_k)$ .  
  Find  $z_k := \arg \min \{ \frac{\ell}{\sigma} d(x) + \sum_{i=0}^k \frac{i+1}{2} [f(x_i) + \langle \nabla f(x_i), x - x_i \rangle] \mid x \in \Omega \}$ .  
  Set  $x_{k+1} := \frac{2}{k+3} z_k + \frac{k+1}{k+3} y_k$ .  
  Set  $k := k + 1$   
**until a stopping criteria is satisfied.**  
OUTPUT:  $y_k$ .

For simplicity, we choose  $d(x) = \frac{\sigma}{2}\|x - x_0\|^2$ , where  $x_0 \in \Omega$  and  $\sigma = 1$ . Following the proof of Proposition 2.2, it is not hard to see that

$$y_k = T_\Omega(x_k) = \Pi\left(x_k - \frac{\nabla f(x_k)}{\ell}; \Omega\right).$$

Moreover,

$$z_k = \Pi\left(x_0 - \frac{1}{\ell} \sum_{i=0}^k \frac{i+1}{2} \nabla f(x_i); \Omega\right).$$

We continue with another important tool of convex optimization and computational statistics called the *MM Principle (minimization majorization)*; see [8, 11, 15] and the references therein. Here we provide a more general version. Let  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  be a convex function and let  $\Omega$  be a nonempty closed convex subset of  $\mathbb{R}^n$ . Consider the optimization problem

$$(7) \quad \text{minimize } f(x) \text{ subject to } x \in \Omega.$$

Let  $\mathcal{M} : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$  and let  $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$  be a set-valued mapping with

$$f(x) \leq \mathcal{M}(x, z) \quad \forall z \in F(x), \text{ and } \mathcal{M}(x, z) = f(x) \quad \forall z \in F(x).$$

The MM algorithm to solve (7) is given by

$$\text{Choose } z_k \in F(x_k) \text{ and find } x_{k+1} \in \arg \min\{\mathcal{M}(x, z_k) \mid x \in \Omega\}.$$

Then

$$f(x_{k+1}) \leq \mathcal{M}(x_{k+1}, z_k) \leq \mathcal{M}(x_k, z_k) = f(x_k).$$

Finding an appropriate majorization is an important step in this algorithm. It has been shown in [7] that the MM Principle provides an effective tool for solving the generalized Fermat-Torricelli problem. In what follows, we apply the MM Principle in combination with Nesterov's smoothing technique and accelerated gradient method to solve generalized Fermat-Torricelli problems in many different settings.

### 3 Generalized Fermat-Torricelli Problems Involving Points

Let  $\Omega$  be a nonempty closed convex subset of  $\mathbb{R}^n$  and let  $a_i \in \mathbb{R}^n$  for  $i = 1, \dots, m$ . In this section we consider the following generalized version of the Fermat-Torricelli problem:

$$(8) \quad \text{minimize } H(x) := \sum_{i=1}^m \sigma_F(x - a_i) \text{ subject to } x \in \Omega.$$

Let us start with some properties of the function  $\sigma_F$  used in problem (8). The following proposition follows directly from the definition of the function (1).

**Proposition 3.1** Consider the function (1). The following properties hold for all  $u, v \in \mathbb{R}^n$  and  $\lambda \geq 0$ :

- (i)  $|\sigma_F(u) - \sigma_F(v)| \leq \|F\| \|u - v\|$ , where  $\|F\| := \sup\{\|f\| \mid f \in F\}$ .
- (ii)  $\sigma_F(u + v) \leq \sigma_F(u) + \sigma_F(v)$ .
- (iii)  $\sigma_F(\lambda u) = \lambda \sigma_F(u)$ , and  $\sigma_F(u) = 0$  if and only if  $u = 0$ .
- (iv)  $\sigma_F$  is a norm if we assume additionally that  $F$  is symmetric, i.e.,  $F = -F$ .
- (v)  $\ell \|u\| \leq \sigma_F(u)$ , where  $\ell := \sup\{r > 0 \mid \mathbb{B}(0; r) \subset F\}$ .

In what follows we study the existence and uniqueness of the optimal solution of problem (8). The following definition and the proposition afterward are important for this purpose.

**Definition 3.2** We say that  $F$  is normally smooth if for every  $x \in \text{bd } F$  there exists  $a_x \in \mathbb{R}^n$  such that  $N(x; F) = \text{cone}\{a_x\}$ .

Given a positive definite matrix  $A$ , define

$$\|x\|_X := \sqrt{x^T A x}.$$

It is not hard to see that  $F := \{x \in \mathbb{R}^n \mid \|x\|_X \leq 1\}$  is normally smooth. Indeed,  $N(x; F) = \text{cone}\{Ax\}$  if  $\|x\|_X = 1$ ; see [17, Proposition 2.48].

Define the set

$$\mathbb{B}_F^* := \{u \in \mathbb{R}^n \mid \sigma_F(u) \leq 1\}$$

and recall that a convex subset  $\Omega$  of  $\mathbb{R}^n$  is called *strictly convex* if  $tu + (1 - t)v \in \text{int } \Omega$  whenever  $u, v \in \Omega$ ,  $u \neq v$ , and  $t \in (0, 1)$ .

**Proposition 3.3** We have that  $F$  is normally smooth if and only if  $\mathbb{B}_F^*$  is strictly convex.

**Proof.** Fix any  $u, v \in \mathbb{B}_F^*$  with  $u \neq v$  and  $t \in (0, 1)$ . Let us show that  $tu + (1 - t)v \in \text{int } \mathbb{B}_F^*$ . We only need to consider the case where  $\sigma_F(u) = \sigma_F(v) = 1$ . Fix  $\bar{x}, \bar{y} \in F$  such that

$$\langle u, \bar{x} \rangle = \sigma_F(u) = 1 \text{ and } \langle v, \bar{y} \rangle = \sigma_F(v) = 1,$$

and fix  $e \in F$  such that

$$\langle tu + (1 - t)v, e \rangle = \sigma_F(tu + (1 - t)v).$$

It is obvious that  $\sigma_F(tu + (1 - t)v) \leq 1$ . By contradiction, suppose that  $\sigma_F(tu + (1 - t)v) = 1$ . Then

$$1 = \langle tu + (1 - t)v, e \rangle = t\langle u, e \rangle + (1 - t)\langle v, e \rangle \leq t\langle u, \bar{x} \rangle + (1 - t)\langle v, \bar{y} \rangle = 1.$$

This implies  $\langle u, e \rangle = \langle u, \bar{x} \rangle = 1 = \sigma_F(u)$  and  $\langle v, e \rangle = \langle v, \bar{y} \rangle = 1 = \sigma_F(v)$ . Then

$$\langle u, x \rangle \leq \langle u, e \rangle \text{ for all } x \in F,$$

which implies  $u \in N(e; F)$ . Similarly,  $v \in N(e; F)$ . Since  $F$  is normally smooth,  $u = \lambda v$ , where  $\lambda > 0$ . Thus,

$$1 = \langle u, e \rangle = \langle \lambda v, e \rangle = \lambda \langle v, e \rangle = \lambda.$$

Hence  $\lambda = 1$  and  $u = v$ , a contradiction.

Now suppose that  $\mathbb{B}_F^*$  is strictly convex. Fix any  $u, v \in N(\bar{x}; F)$  with  $u, v \neq 0$ . Let  $\alpha := \sigma_F(u)$  and  $\beta := \sigma_F(v)$ . Then

$$\langle u, x \rangle \leq \langle u, \bar{x} \rangle \text{ for all } x \in F$$

and

$$\langle v, x \rangle \leq \langle v, \bar{x} \rangle \text{ for all } x \in F.$$

It follows that  $\langle u, \bar{x} \rangle = \alpha$  and  $\langle v, \bar{x} \rangle = \beta$ . Moreover,

$$\sigma_F(u + v) \geq \langle u, \bar{x} \rangle + \langle v, \bar{x} \rangle = \alpha + \beta = \sigma_F(u) + \sigma_F(v),$$

and hence  $\sigma_F(u + v) = \sigma_F(u) + \sigma_F(v)$ . We have  $u/\alpha, v/\beta \in \mathbb{B}_F^*$  and

$$\sigma_F\left(\frac{u}{\alpha} \frac{\alpha}{\alpha + \beta} + \frac{v}{\beta} \frac{\beta}{\alpha + \beta}\right) = 1.$$

Since  $\mathbb{B}_F^*$  is strictly convex, one has  $\frac{u}{\alpha} = \frac{v}{\beta}$ , and hence  $u = \lambda v$ , where  $\lambda := \alpha/\beta > 0$ . The proof is now complete.  $\square$

**Remark 3.4** Suppose that  $F$  is normally smooth. It follows from the proof of Proposition 3.3 that for  $u, v \in \mathbb{R}^n$  with  $u, v \neq 0$ , one has that  $\sigma_F(u + v) = \sigma_F(u) + \sigma_F(v)$  if and only if  $u = \lambda v$  for some  $\lambda > 0$ .

The proposition below gives sufficient conditions that guarantee the uniqueness of an optimal solution of (8).

**Proposition 3.5** *Suppose that  $F$  is normally smooth. If for any  $x, y \in \Omega$  with  $x \neq y$ , the line connecting  $x$  and  $y$ ,  $\mathcal{L}(x, y)$ , does not contain at least one of the points  $a_i$  for  $i = 1, \dots, m$ , then problem (8) has a unique optimal solution.*

**Proof.** It is not hard to see that for any  $\alpha \in \mathbb{R}$ , the set

$$\mathcal{L}_\alpha := \{x \in \Omega \mid H(x) \leq \alpha\}$$

is compact, and so (8) has an optimal solution since  $H$  is continuous. Let us show that the assumptions made guarantee that  $H$  is strictly convex on  $\Omega$ , and hence (8) has a unique optimal solution.

By contradiction, suppose that there exist  $\bar{x}, \bar{y} \in \Omega$  with  $\bar{x} \neq \bar{y}$  and  $t \in (0, 1)$  such that

$$H(t\bar{x} + (1 - t)\bar{y}) = tH(\bar{x}) + (1 - t)H(\bar{y}).$$

Then

$$\begin{aligned} \sigma_F(t(\bar{x} - a_i) + (1 - t)(\bar{y} - a_i)) &= t\sigma_F(\bar{x} - a_i) + (1 - t)\sigma_F(\bar{y} - a_i) \\ &= \sigma_F(t(\bar{x} - a_i)) + \sigma_F((1 - t)(\bar{y} - a_i)) \text{ for all } i = 1, \dots, m. \end{aligned}$$

If  $\bar{x} = a_i$  or  $\bar{y} = a_i$ , then  $a_i \in \mathcal{L}(\bar{x}, \bar{y})$  obviously. Otherwise, by Remark 3.4, there exists  $\lambda_i > 0$  such that

$$t(\bar{x} - a_i) = \lambda_i(1 - t)(\bar{y} - a_i).$$

This also implies that  $a_i \in \mathcal{L}(\bar{x}, \bar{y})$ . We have seen that  $a_i \in \mathcal{L}(\bar{x}, \bar{y})$  for all  $i = 1, \dots, m$ . This contradiction shows that (8) has a unique optimal solution.  $\square$

Let us consider the smooth approximation function given by

$$(9) \quad H_\mu(x) = \sum_{i=1}^m \left( \frac{\|x - a_i\|^2}{2\mu} + \langle x - a_i, \bar{u} \rangle - \frac{\mu}{2} [d(\bar{u} + \frac{x - a_i}{\mu}; F)]^2 \right),$$

where  $\bar{u} \in F$ .

**Proposition 3.6** *The function  $H_\mu$  defined by (9) is continuously differentiable on  $\mathbb{R}^n$  with its gradient given by*

$$\nabla H_\mu(x) = \sum_{i=1}^m \Pi(\bar{u} + \frac{x - a_i}{\mu}; F).$$

*Its gradient is a Lipschitz function with constant*

$$\mathcal{L}_\mu = \frac{m}{\mu}.$$

*Moreover, one has the following estimate*

$$H_\mu(x) \leq H(x) < H_\mu(x) + m \frac{\mu}{2} [D(\bar{u}; F)]^2 \text{ for all } x \in \mathbb{R}^n.$$

**Proof.** Given  $b \in \mathbb{R}^n$ , define the function on  $\mathbb{R}^n$  given by

$$f(x) := \sigma_F(x - b) = \max\{\langle x - b, u \rangle \mid u \in F\}, x \in \mathbb{R}^n.$$

Consider the prox-function

$$d(u) = \frac{1}{2} \|u - \bar{u}\|^2.$$

Applying Proposition 2.2 with  $Ax = x$ , one has that the function  $f_\mu$  is continuously differentiable on  $\mathbb{R}^n$  with its gradient given by

$$\nabla f_\mu(x) = u_\mu(x) = \Pi(\bar{u} + \frac{x - b}{\mu}; F).$$

Moreover, the gradient  $\nabla f_\mu$  is a Lipschitz function with constant

$$\ell_\mu = \frac{1}{\mu}.$$

The explicit formula for  $f_\mu$  is

$$f_\mu(x) = \frac{\|x - b\|^2}{2\mu} + \langle x - b, \bar{u} \rangle - \frac{\mu}{2} [d(\bar{u} + \frac{x - b}{\mu}; F)]^2.$$

The conclusions then follow easily.  $\square$

We are now ready to write a pseudocode for solving the Fermat-Torricelli problem (8).

**Algorithm 2.**

INPUT:  $a_i$  for  $i = 1, \dots, m$ ,  $\mu$   
INITIALIZE: Choose  $x_0 \in \Omega$  and set  $\ell = \frac{m}{\mu}$ .  
Set  $k = 0$   
**Repeat the following**  
    Compute  $\nabla H_\mu(x_k) = \sum_{i=1}^m \Pi(\bar{u} + \frac{x_k - a_i}{\mu}; F)$ .  
    Find  $y_k := \Pi(x_k - \frac{1}{\ell} \nabla H_\mu(x_k); \Omega)$ .  
    Find  $z_k := \Pi(x_0 - \frac{1}{\ell} \sum_{i=0}^k \frac{i+1}{2} \nabla H_\mu(x_i); \Omega)$ .  
    Set  $x_{k+1} := \frac{2}{k+3} z_k + \frac{k+1}{k+3} y_k$ .  
**until a stopping criteria is satisfied.**

**Remark 3.7** When implementing Nesterov's accelerated gradient method, in order to get a more effective algorithm, instead of using a fixed smoothing parameter  $\mu$ , we often change  $\mu$  during the optimization. The general optimization scheme is

INITIALIZE:  $x_0 \in \Omega$ ,  $\mu_0 > 0$ ,  $\mu_* > 0$ ,  $\sigma \in (0, 1)$   
Set  $k = 0$ .  
**Repeat the following**  
    Apply Nesterov's accelerated gradient method with  $\mu = \mu_k$  and starting point  $x_k$   
    Update  $\mu_{k+1} = \sigma \mu_k$   
**until  $\mu \leq \mu_*$**

**Example 3.8** In the case where  $F$  is the closed unit Euclidean ball,  $\sigma_F(x) = \|x\|$  is the Euclidean norm and

$$\Pi(x; F) = \begin{cases} \left\{ \frac{x}{\|x\|} \right\}, & \|x\| > 1 \\ \{x\}, & \|x\| \leq 1. \end{cases}$$

Consider the  $\ell_1$ -norm on  $\mathbb{R}^n$ . For any  $x \in \mathbb{R}^n$ , one has

$$\|x\|_1 = \max\{\langle x, u \rangle \mid \|u\|_\infty \leq 1\},$$

In this case,

$$F = \{x \in \mathbb{R}^n \mid |x_i| \leq 1 \text{ for all } i = 1, \dots, n\}.$$

The smoothing of the function  $f(x) := \|x\|_1$  depends on the Euclidean projection to the set  $F$ , which can be found explicitly. In fact, for any  $u \in \mathbb{R}^n$ , one has

$$\Pi(u; F) = \{v \in \mathbb{R}^n \mid v_i = \text{median}\{u_i, 1, -1\}\}.$$

Now we consider the  $\ell_\infty$ -norm in  $\mathbb{R}^n$ . For any  $x \in \mathbb{R}^n$ , one has

$$\|x\|_\infty = \max\{\langle x, u \rangle \mid \|u\|_1 \leq 1\}.$$

In this case,

$$F = \{x \in \mathbb{R}^n \mid \|x\|_1 \leq 1\}.$$

It is straightforward to find the Euclidean projection of a point to  $F$  in two and three dimensions. In the case of high dimensions, there are available algorithms to find an approximation of the projection; see, e.g., [9].

## 4 Generalized Fermat-Torricelli Problems Involving Sets

In this section we consider generalized Fermat-Torricelli problems that involves sets. Consider the following optimization problem:

$$(10) \quad \text{minimize } T(x) := \sum_{i=1}^m d_F(x; \Omega_i) \text{ subject to } x \in \Omega,$$

where  $\Omega$  and  $\Omega_i$  for  $i = 1, \dots, m$  are nonempty closed convex sets and at least one of them is bounded. This assumption guarantees that the problem has an optimal solution. The sets  $\Omega_i$  for  $i = 1, \dots, m$  are called the *target sets*, and the set  $\Omega$  is called the *constraint set*.

The *generalized projection* from a point  $x$  to  $\Omega$  is defined based on the distance function (2) as follows

$$(11) \quad \pi_F(x; \Omega) := \{w \in \Omega \mid \sigma_F(x - w) = d_F(x; \Omega)\}.$$

Note that this set is not necessarily a singleton in general.

Before investigating problem (10), we study some important properties of the generalized distance function (2) and the generalized projection (11) to be used in the sequel.

**Proposition 4.1** *Consider the function (2) and the projection mapping (11). The following properties hold:*

- (i) *For any  $\bar{x} \in \mathbb{R}^n$ , the set  $\pi_F(\bar{x}; \Omega)$  is nonempty.*
- (ii) *If  $\bar{x} \notin \Omega$  and  $\bar{w} \in \pi_F(\bar{x}; \Omega)$ , then  $\bar{w} \in \text{bd } \Omega$ .*
- (iii) *If  $F$  is normally smooth, then  $\pi_F(\bar{x}; \Omega)$  is a singleton, and the projection mapping  $\pi_F(\cdot; \Omega)$  is continuous.*

**Proof.** (i) The proof is straightforward.

(ii) Suppose by contradiction that  $\bar{w} \in \text{int } \Omega$ . Choose  $t \in (0, 1)$  sufficiently small such that

$$w_t := \bar{w} + t(\bar{x} - \bar{w}) \in \Omega.$$

Then

$$\sigma_F(\bar{x} - w_t) = \sigma_F((1 - t)(\bar{x} - \bar{w})) = (1 - t)\sigma_F(\bar{x} - \bar{w}) = (1 - t)d_F(\bar{x}; \Omega) < d_F(\bar{x}; \Omega),$$

which is a contradiction.

(iii) If  $\bar{x} \in \Omega$ , then  $\pi_F(\bar{x}; \Omega) = \{\bar{x}\}$ . Consider the case where  $\bar{x} \notin \Omega$ . Suppose by contradiction that there exist  $\bar{w}_1, \bar{w}_2 \in \pi_F(\bar{x}; \Omega)$  with  $\bar{w}_1 \neq \bar{w}_2$ . Then

$$\gamma := \sigma_F(\bar{x} - \bar{w}_1) = \sigma_F(\bar{x} - \bar{w}_2) > 0.$$

By the positive homogeneity of  $\sigma_F$ ,

$$\frac{\bar{x} - \bar{w}_1}{\gamma} \in \mathbb{B}_F^* \text{ and } \frac{\bar{x} - \bar{w}_2}{\gamma} \in \mathbb{B}_F^*.$$

By Proposition 3.3, the set  $\mathbb{B}_F^*$  is strictly convex, and hence

$$\frac{1}{2}\left(\frac{\bar{x} - \bar{w}_1}{\gamma} + \frac{\bar{x} - \bar{w}_2}{\gamma}\right) \in \text{int } \mathbb{B}_F^*.$$

This implies

$$\frac{\bar{x} - (\bar{w}_1 + \bar{w}_2)/2}{\gamma} \in \text{int } \mathbb{B}_F^*.$$

It follows again by the homogeneity of  $\sigma_F$  that

$$\sigma_F(\bar{x} - (\bar{w}_1 + \bar{w}_2)/2) < \gamma = d_F(\bar{x}; \Omega),$$

which is a contradiction. It is not hard to show that  $\pi_F(\cdot; \Omega)$  is continuous by a sequential argument.  $\square$

To continue, we recall some basic concepts and results of convex analysis. A systematic development of convex analysis can be found, for instance, in [26]. Let  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  be a convex function. For  $\bar{x} \in \mathbb{R}^n$ , a *subgradient* of  $f$  at  $\bar{x}$  is a vector  $v \in \mathbb{R}^n$  that satisfies

$$\langle v, x - \bar{x} \rangle \leq f(x) - f(\bar{x}) \text{ for all } x \in \mathbb{R}^n.$$

The set of all subgradients of  $f$  at  $\bar{x}$  is called the *subdifferential* of  $f$  at this point and is denoted by  $\partial f(\bar{x})$ .

Let  $\Omega$  be a nonempty closed convex subset of  $\mathbb{R}^n$  and let  $\bar{x} \in \Omega$ . The *normal cone* in the sense of convex analysis to  $\Omega$  at  $\bar{x}$  is defined by

$$N(\bar{x}; \Omega) := \{v \in \mathbb{R}^n \mid \langle v, x - \bar{x} \rangle \leq 0 \text{ for all } x \in \Omega\}.$$

It is well-known that a convex function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  has an absolute minimum on a nonempty closed convex set  $\Omega$  at  $\bar{x} \in \Omega$  if and only if

$$0 \in \partial f(\bar{x}) + N(\bar{x}; \Omega).$$

For a finite number of convex functions  $f_i : \mathbb{R}^n \rightarrow \mathbb{R}$  for  $i = 1, \dots, m$ , one has

$$\partial\left(\sum_{i=1}^m f_i\right)(x) = \sum_{i=1}^m \partial f_i(x), \quad x \in \mathbb{R}^n.$$

Moreover, the normal cone mapping  $N(\cdot; \Omega)$  has closed graph in the sense that for any sequence  $x_k \rightarrow \bar{x}$  and  $v_k \rightarrow \bar{v}$  where  $v_k \in N(x_k; \Omega)$ , one has that  $\bar{v} \in N(\bar{x}; \Omega)$ .

A convex set  $F$  is said to be *normally round* if  $N(x; F) \neq N(y; F)$  whenever  $x, y \in \text{bd } F$ ,  $x \neq y$ .

**Proposition 4.2** *Consider the function (2). Then the following properties hold:*

- (i)  $|d_F(x; \Omega) - d_F(y; \Omega)| \leq \|F\| \|x - y\|$  for all  $x, y \in \mathbb{R}^n$ .
- (ii) *The function  $d_F(\cdot; \Omega)$  is convex and for any  $\bar{x} \in \mathbb{R}^n$ ,*

$$\partial d_F(\bar{x}; \Omega) = \partial \sigma_F(\bar{x} - \bar{w}) \cap N(\bar{w}; \Omega),$$

where  $\bar{w} \in \pi_F(\bar{x}; \Omega)$  and this representation does not depend on the choice of  $\bar{w}$ .

(iii) If  $F$  is normally smooth and round, then  $\sigma_F(\cdot)$  is differentiable at any nonzero point, and  $d_F(\cdot; \Omega)$  is differentiable on the complement of  $\Omega$  with

$$\nabla d_F(\bar{x}; \Omega) = \nabla \sigma_F(\bar{x} - \bar{w}),$$

where  $\bar{x} \notin \Omega$  and  $\bar{w} := \pi_F(\bar{x}; \Omega)$ . Moreover,  $d_F(\cdot; \Omega)$  is continuously differentiable on  $\Omega^c$ .

**Proof.** (i) This conclusion follows from the subadditivity and the Lipschitz property of the function  $\sigma_F$ .

(ii) The function  $d_F(\cdot; \Omega)$  can be expressed as the following infimal convolution

$$d_F(x; \Omega) = \inf\{\sigma_F(x - w) + \delta(w; \Omega) \mid w \in \mathbb{R}^n\} = (\sigma_F \oplus g)(x),$$

where  $g(x) := \delta(x; \Omega)$  is the indicator function associated with  $\Omega$ . For any  $\bar{w} \in \pi_F(\bar{x}; \Omega)$ , one has

$$\sigma_F(\bar{x} - \bar{w}) + g(\bar{w}) = \sigma_F(\bar{x} - \bar{w}) = d_F(\bar{x}; \Omega).$$

By [17, Corollary 2.65],

$$\partial d_F(\bar{x}; \Omega) = \partial \sigma_F(\bar{x} - \bar{w}) \cap \partial g(\bar{w}) = \partial \sigma_F(\bar{x} - \bar{w}) \cap N(\bar{w}; \Omega).$$

(iii) Let us first prove the differentiability of  $\sigma_F(\cdot)$  at  $\bar{x} \neq 0$ . From [17, Theorem 2.68], one has

$$\partial \sigma_F(\bar{x}) = S(\bar{x}),$$

where  $S(\bar{x}) := \{p \in F \mid \langle \bar{x}, p \rangle = \sigma_F(\bar{x})\}$ . We will show that  $S(\bar{x})$  is a singleton. By contradiction, suppose that there exist  $p_1, p_2 \in S(\bar{x})$  with  $p_1 \neq p_2$ . From the definition, one has

$$\bar{x} \in N(p_1; F) = \text{cone}\{a_1\} \text{ and } \bar{x} \in N(p_2; F) = \text{cone}\{a_2\}.$$

Then there exist  $\lambda_1, \lambda_2 > 0$  such that  $\bar{x} = \lambda_1 a_1 = \lambda_2 a_2$ , and hence  $N(p_1; F) = N(p_2; F)$ , a contradiction to the normally smooth and round property of  $F$ . Thus,  $\partial \sigma_F(\bar{x}) = S(\bar{x})$  is a singleton, and hence  $\sigma_F$  is differentiable at  $\bar{x}$  by [17, Theorem 3.3].

Observe that the set  $\partial d_F(\bar{x}; \Omega)$  is nonempty. Since  $\partial d_F(\bar{x}; \Omega) = \partial \sigma_F(\bar{x} - \bar{w}) \cap N(\bar{w}; \Omega) = \nabla \sigma_F(\bar{x} - \bar{w}) \cap N(\bar{w}; \Omega)$ , it is obvious that  $\nabla \sigma_F(\bar{x} - \bar{w}) \in N(\bar{w}; \Omega)$  and  $\partial d_F(\bar{x}; \Omega) = \{\nabla \sigma_F(\bar{x} - \bar{w})\}$ . Then the differentiability of  $d_F(\cdot; \Omega)$  at  $\bar{x}$  follows from [17, Theorem 3.3]. Since  $\Omega^c$  is an open set and  $\partial d_F(x; \Omega)$  is a singleton for every  $x \in \Omega^c$ , the function  $d_F(\cdot; \Omega)$  is continuously differentiable on this set; see the corollary of [10, Proposition 2.2.2].  $\square$

As a corollary, we obtain the following well-known formula for subdifferential of the distance function (3).

**Corollary 4.3** *For a nonempty closed convex set  $\Omega$ , the following representation holds:*

$$\partial d(\bar{x}; \Omega) = \begin{cases} N(\bar{x}; \Omega) \cap \mathbb{B} & \text{if } \bar{x} \in \Omega, \\ \left\{ \frac{\bar{x} - \Pi(\bar{x}; \Omega)}{d(\bar{x}; \Omega)} \right\} & \text{if } \bar{x} \notin \Omega. \end{cases}$$

The following proposition gives sufficient conditions that guarantee the uniqueness of an optimal solution of problem (10).

**Proposition 4.4** *Suppose that  $F$  is normally smooth and the target sets  $\Omega_i$  for  $i = 1, \dots, m$  are strictly convex with at least one of them being bounded. If for any  $x, y \in \Omega$  with  $x \neq y$  the line connecting  $x$  and  $y$ ,  $\mathcal{L}(x, y)$ , does not intersect at least one of the target sets. Then problem (10) has a unique optimal solution.*

**Proof.** It is not hard to prove that if one of the target sets is bounded, then each level set  $\{x \in \Omega \mid T(x) \leq \alpha\}$  is bounded. Thus, (10) has an optimal solution. It suffices to show that  $T$  is strictly convex on  $\Omega$  under the given assumptions. By contradiction, suppose that  $T$  is not strictly convex. Then there exist  $\bar{x}, \bar{y} \in \Omega$  and  $t \in (0, 1)$  with  $\bar{x} \neq \bar{y}$  and

$$T(t\bar{x} + (1-t)\bar{y}) = tT(\bar{x}) + (1-t)T(\bar{y}).$$

This implies  $d_F(t\bar{x} + (1-t)\bar{y}; \Omega_i) = td_F(\bar{x}; \Omega_i) + (1-t)d_F(\bar{y}; \Omega_i)$  for all  $i = 1, \dots, m$ . Choose  $i_0 \in \{1, \dots, m\}$  such that  $\mathcal{L}(\bar{x}, \bar{y}) \cap \Omega_{i_0} = \emptyset$ . Let  $\bar{w}_1 := \pi_F(\bar{x}; \Omega_{i_0})$  and  $\bar{w}_2 := \pi_F(\bar{y}; \Omega_{i_0})$ . Then

$$\begin{aligned} d_F(t\bar{x} + (1-t)\bar{y}; \Omega_{i_0}) &= td_F(\bar{x}; \Omega_{i_0}) + (1-t)d_F(\bar{y}; \Omega_{i_0}) \\ &= t\sigma_F(\bar{x} - \bar{w}_1) + (1-t)\sigma_F(\bar{y} - \bar{w}_2) \\ &\geq \sigma_F((t\bar{x} + (1-t)\bar{y}) - (t\bar{w}_1 + (1-t)\bar{w}_2)). \end{aligned}$$

It follows that  $t\bar{w}_1 + (1-t)\bar{w}_2 = \pi_F(t\bar{x} + (1-t)\bar{y}; \Omega_{i_0}) \in \text{bd } \Omega_{i_0}$ . By the strict convexity of  $\Omega_{i_0}$ , one has  $\bar{w}_1 = \bar{w}_2 =: \bar{w}$ , and hence

$$\sigma_F(t(\bar{x} - \bar{w}) + (1-t)(\bar{y} - \bar{w})) = \sigma_F(t(\bar{x} - \bar{w})) + \sigma_F((1-t)(\bar{y} - \bar{w})).$$

Following the proof of Proposition 3.5 implies  $\bar{w} \in \mathcal{L}(\bar{x}, \bar{y})$ , a contradiction.  $\square$

Let us now apply the MM Principle to the generalized Fermat-Torricelli problem. We rely on the following properties:

- (i)  $d_F(x; \Omega) = \sigma_F(x - w)$  for all  $w \in \pi_F(x; \Omega)$ .
- (ii)  $d_F(x; \Omega) \leq \sigma_F(x - w)$  for all  $w \in \pi_F(y; \Omega)$ .

Consider the set-valued mapping

$$F(x) := (\pi_F(x; \Omega_1), \dots, \pi_F(x; \Omega_m)).$$

Then cost function  $T(x)$  is majorized by

$$T(x) \leq \mathcal{M}(x, w) := \sum_{i=1}^m \sigma_F(x - w^i), \quad w = (w^1, \dots, w^m) \in F(y),$$

which satisfies  $\mathcal{M}(x, w) = T(x)$  whenever  $w \in F(x)$ .

Thus, the MM iteration is given by

$$x_{k+1} \in \arg \min \{ \mathcal{M}(x, w_k) \mid x \in \Omega \}, \quad w_k \in F(x_k).$$

This algorithm can be written more explicitly as follows.

Figure 1: MM Algorithm for a Generalized Fermat-Torricelli Problem

**Algorithm 3.**

INPUT:  $m$  target sets  $\Omega_i, i = 1, \dots, m$ .  
INITIALIZE:  $x_0 \in \Omega$ .  
Set  $k = 0$ .  
**Repeat the following**  
    Find  $y_{k,i} \in \pi_F(x_k; \Omega_i)$   
    Solve the following problem with a stopping criterion  
        
$$\min_{x \in \Omega} \sum_{i=1}^m \sigma_F(x - y_{k,i}),$$
  
    and denote its solution by  $x_{k+1}$ .  
**until a stopping criterion is satisfied.**

**Remark 4.5** Consider Fermat-Torricelli problem:

$$(12) \quad \text{minimize } \varphi(x) := \sum_{i=1}^m \|x - a_i\|, \quad x \in \Omega.$$

For  $x \notin \{a_1, \dots, a_m\}$ ,

$$\nabla \varphi(x) := \sum_{i=1}^m \frac{x - a_i}{\|x - a_i\|}.$$

Solving the equation  $\nabla \varphi(x) = 0$  yields

$$x = \frac{\sum_{i=1}^m \frac{a_i}{\|x - a_i\|}}{\sum_{i=1}^m \frac{1}{\|x - a_i\|}}$$

If  $x \notin \{a_1, \dots, a_m\}$ , define

$$F(x) := \frac{\sum_{i=1}^m \frac{a_i}{\|x - a_i\|}}{\sum_{i=1}^m \frac{1}{\|x - a_i\|}}.$$

Otherwise, put  $F(x) := x$ . The Weiszfeld's algorithm (see [12]) for solving problem (12) is stated as follows: Choose  $x_0 \in \Omega$  and find  $x_{k+1} := \Pi(F(x_k); \Omega)$  for  $k \geq 1$ .

In the case where  $F$  is the closed unit Euclidean ball of  $\mathbb{R}^n$  one has  $\sigma_F(x) = \|x\|$ . To solve the problem

$$\min_{x \in \Omega} \sum_{i=1}^m \|x - y_{k,i}\|$$

in the MM algorithm above, we can also use the Weiszfeld's algorithm or its improvements.

**Proposition 4.6** *Consider the generalized Fermat-Torricelli problem (10) in which  $F$  is normally smooth and round. Let  $\{x_k\}$  be the sequence in the MM algorithm defined by*

$$x_{k+1} := \arg \min \left\{ \sum_{i=1}^m \sigma_F(x - \pi_F(x_k; \Omega_i)) \mid x \in \Omega \right\}.$$

*Suppose that  $\{x_k\}$  converges to  $\bar{x}$  that does not belong to  $\Omega_i$  for  $i = 1, \dots, m$ . Then  $\bar{x}$  is an optimal solution of problem (10).*

**Proof.** Since the sequence  $\{x_k\}$  converges to  $\bar{x}$  that does not belong to  $\Omega_i$  for  $i = 1, \dots, m$ , we can assume that  $x_k \notin \Omega_i$  for  $i = 1, \dots, m$  and for every  $k$ . From the definition of the sequence  $\{x_k\}$ , one has

$$0 \in \sum_{i=1}^m \nabla \sigma_F(x_{k+1} - \pi(x_k; \Omega_i)) + N(x_{k+1}; \Omega).$$

Using the continuity of  $\nabla \sigma_F(\cdot)$  and the projection mapping  $\pi_F(\cdot)$  to nonempty closed convex sets, as well as the closedness of the normal cone mapping, one has

$$0 \in \sum_{i=1}^m \nabla \sigma_F(\bar{x} - \pi(\bar{x}; \Omega_i)) + N(\bar{x}; \Omega).$$

Thus,

$$0 \in \sum_{i=1}^m \partial d_F(\bar{x}; \Omega_i) + N(\bar{x}; \Omega) = \partial T(\bar{x}) + N(\bar{x}; \Omega).$$

It follows that  $\bar{x}$  is also an optimal solution of problem (10).  $\square$

It is of course important to find sufficient conditions that guarantee the convergence of the sequence  $\{x_k\}$ . This can be done using [8, Propostions 1 and 2]; see also [7]. We justify the use of this approach in the following lemma and apply it in the proposition that follows. For simplicity, we assume that the constraint set  $\Omega$  does not intersect any of the target sets  $\Omega_i$  for  $i = 1, \dots, m$ .

**Lemma 4.7** *Consider the generalized Fermat-Torricelli problem (10) in which at least one of the target sets  $\Omega_i$  for  $i = 1, \dots, m$  is bounded and  $F$  is normally smooth and round. Suppose that the constraint set  $\Omega$  does not intersect any of the target sets  $\Omega_i$  for  $i = 1, \dots, m$ , and any  $x, y \in \Omega$  with  $x \neq y$  the line connecting  $x$  and  $y$ ,  $\mathcal{L}(x, y)$ , does not intersect at least one of the target sets. For any  $x \in \Omega$ , consider the mapping  $\psi : \Omega \rightarrow \Omega$  defined by*

$$\psi(x) := \arg \min \left\{ \sum_{i=1}^m \sigma_F(y - \pi_F(x; \Omega_i)) \mid y \in \Omega \right\}.$$

*Then  $\psi$  is continuous at any point  $\bar{x} \in \Omega$ , and  $T(\psi(x)) < T(x)$  whenever  $x \neq \psi(x)$ .*

**Proof.** Fix any  $x \in \Omega$ . By Proposition 3.5 and from the assumptions made, the function

$$g(y) := \sum_{i=1}^m \sigma_F(y - \pi_F(x; \Omega_i))$$

is strictly convex on  $\Omega$ , so  $\psi(x)$  is the unique solution of the Fermat-Torricelli problem generated by  $\pi_F(x; \Omega_i)$  for  $i = 1, \dots, m$ . Thus,  $\psi$  is a single value mapping. Fix any sequence  $\{x_k\}$  that converges to  $\bar{x}$ . Then  $y_k := \psi(x_k)$  satisfies

$$0 \in \sum_{i=1}^m \nabla \sigma_F(y_k - \pi_F(x_k; \Omega_i)) + N(y_k; \Omega).$$

Since at least one of the sets  $\Omega_i$  for  $i = 1, \dots, m$  is bounded, we can show that the sequence  $\{y_k\}$  is bounded. Indeed, suppose that  $\Omega_1$  is bounded and  $\{y_k\}$  is unbounded. Then there exists a subsequence  $\{y_{k_p}\}$  such that  $\|y_{k_p}\| \rightarrow \infty$  as  $p \rightarrow \infty$ . For sufficiently large  $p$  and a fixed  $y \in \Omega$ , since  $y_{k_p} = \arg \min\{\sum_{i=1}^m \sigma_F(y - \pi_F(x_{k_p}; \Omega_i)) \mid y \in \Omega\}$ , we have

$$\begin{aligned} \sum_{i=1}^m \sigma_F(y - \pi_F(x_{k_p}; \Omega_i)) &\geq \sum_{i=1}^m \sigma_F(y_{k_p} - \pi_F(x_{k_p}; \Omega_i)) \geq \sigma_F(y_{k_p} - \pi_F(x_{k_p}; \Omega_1)) \\ &\geq \ell \|y_{k_p} - \pi_F(x_{k_p}; \Omega_1)\| \geq \ell d_F(y_{k_p}; \Omega_1). \end{aligned}$$

Let  $p \rightarrow \infty$ , one obtains a contradiction showing that  $\{y_k\}$  is bounded.

Now fix any subsequence  $\{y_{k_\ell}\}$  of  $\{y_k\}$  that converges to  $\bar{y} \in \Omega$ . Then

$$0 \in \sum_{i=1}^m \nabla \sigma_F(y_{k_\ell} - \Pi(x_{k_\ell}; \Omega_i)) + N(y_{k_\ell}; \Omega),$$

which implies

$$0 \in \sum_{i=1}^m \nabla \sigma_F(\bar{y} - \pi_F(\bar{x}; \Omega_i)) + N(\bar{y}; \Omega).$$

Therefore,  $\bar{y} = \psi(\bar{x})$ . It follows that  $y_k = \psi(x_k)$  converges to  $\bar{y} = \psi(\bar{x})$ , so  $\psi$  is continuous at  $\bar{x}$ . Fix any  $x \in \Omega$  such that  $x \neq \psi(x)$ . Since the function  $g(y)$  is strictly convex and  $\psi(x)$  is its unique minimizer on  $\Omega$ , one has that

$$\begin{aligned} T(\psi(x)) &= \sum_{i=1}^m d_F(\psi(x); \Omega_i) \leq \sum_{i=1}^m \sigma_F(\psi(x) - \pi_F(x; \Omega_i)) \\ &< \sum_{i=1}^m \sigma_F(x - \pi_F(x; \Omega_i)) = T(x). \end{aligned}$$

The proof is now complete.  $\square$

Let us present below a convergence theorem for the MM algorithm.

**Proposition 4.8** *Consider the generalized Fermat-Torricelli problem (10) in the setting of Lemma 4.7. Then any subsequential limit of the sequence  $\{x_k\}$  is an optimal solution  $\bar{x}$  of problem (10). If we assume additionally that  $\Omega_i$  for  $i = 1, \dots, m$  are strictly convex, then  $\{x_k\}$  converges to the unique optimal solution of the problem.*

**Proof.** In the setting of this proposition, [8, Proposition 1] implies that  $\|x_{k+1} - x_k\| \rightarrow 0$ . From the assumptions made, it is not hard to see that  $\{x_k\}$  is a bounded sequence. Let  $\{x_{k_\ell}\}$  be a subsequence of  $\{x_k\}$  that converges to some  $\bar{x}'$ . Note that  $\|x_{k+1} - x_k\| \rightarrow 0$  implies  $\{x_{k_\ell+1}\}$  also converges to  $\bar{x}'$  as  $\ell \rightarrow \infty$ . Without loss of generality, we can assume that  $x_{k_\ell} \notin \Omega_i$  for all  $i = 1, \dots, m$  and for all  $\ell$ . From the definition of the sequence  $\{x_k\}$ , one has

$$0 \in \sum_{i=1}^m \nabla \sigma_F(x_{k_\ell+1} - \pi_F(x_{k_\ell}; \Omega_i)) + N(x_{k_\ell+1}; \Omega).$$

Then

$$0 \in \sum_{i=1}^m \nabla \sigma_F(\bar{x}' - \pi_F(\bar{x}'; \Omega_i)) + N(\bar{x}'; \Omega).$$

Thus,

$$0 \in \sum_{i=1}^m \partial d_F(\bar{x}'; \Omega_i) + N(\bar{x}'; \Omega) = \partial T(\bar{x}') + N(\bar{x}'; \Omega).$$

Therefore  $\bar{x}'$  is an optimal solution of problem (10).

If  $\Omega_i$  for  $i = 1, \dots, m$  are strictly convex, then problem 10 has a unique optimal solution  $\bar{x}$  by Proposition 4.4. Thus,  $x' = \bar{x}$  and the original sequence  $\{x_k\}$  converges to  $\bar{x}$ .  $\square$

It is important to note that the algorithm may not converge in general. Our examples partially answer the question raised in the conclusion remarks of [8].

**Example 4.9** Let  $\Omega_1$  and  $\Omega_2$  be subsets of  $\mathbb{R}^2$  defined by

$$\Omega_1 := \{(x_1, x_2) \in \mathbb{R}^2 \mid x_2 \geq 1\} \text{ and } \Omega_2 := \{(x_1, x_2) \in \mathbb{R}^2 \mid x_2 \leq -1\}.$$

Consider the generalized Fermat-Torricelli for two sets  $\Omega_1$  and  $\Omega_2$  generated by the  $\ell_\infty$  norm. Starting from  $x_0 = (0, 0)$ . Choose  $y_{0,1} = (1, 1)$  and  $y_{0,2} = (1, -1)$ . Then  $x_1 = (1, 0)$  is an optimal solution of the generalized Fermat-Torricelli problem for two points  $y_{0,1}$  and  $y_{0,2}$  generated by the  $\ell_\infty$  norm. Similarly, we can choose  $y_{1,1} = (2, 1)$ ,  $y_{1,2} = (2, -1)$ , and  $x_2 = (2, 0)$ . Repeating this process, one sees  $x_k = (k, 0)$  is a sequence of solutions of the *majorizations*, which does not has any convergence subsequence.

In the example above, we have the convergence of the optimal values of the majorizations. However, it is not the case in the example below.

**Example 4.10** Let  $\Omega_1$  and  $\Omega_2$  be subsets of  $\mathbb{R}^2$  defined by

$$\Omega_1 := \{(x_1, 0) \in \mathbb{R}^2 \mid x_1 \geq 0\} \text{ and } \Omega_2 := \{(0, x_2) \in \mathbb{R}^2 \mid x_2 \geq 0\}.$$

Consider the generalized Fermat-Torricelli for two sets  $\Omega_1$  and  $\Omega_2$  generated by the  $\ell_\infty$ -norm. It is not hard to see that  $(0, 0)$  is the unique optimal solution of this problem. Starting from  $x_0 = (1/2, 1/2)$ . Choose  $y_{0,1} = (1, 0)$  and  $y_{0,2} = (0, 1)$ . Then  $x_1 = (1/2, 1/2)$  is an optimal solution of the generalized Fermat-Torricelli problem for two points  $y_{0,1}$  and  $y_{0,2}$  generated by the  $\ell_\infty$ -norm. Obviously, if we choose the projections in this way, the sequence of optimal solutions and optimal values of the majorizations do not converge to the optimal solution and the optimal value of the problem. However, if the projections are chosen differently, we may obtain the convergence of the algorithm.

Let us consider an example in which the convergence for the MM method is not guaranteed even if we consider generalized Fermat-Torricelli problems generated by the Euclidean norm.

**Example 4.11** Let  $\Omega_i$  for  $i = 1, 2, 3$  be three Euclidean balls of  $\mathbb{R}^2$  defined with radii 1 and centers at  $(-4, 0)$ ,  $(0, 0)$ , and  $(4, 0)$ , respectively. Using the starting point  $x_0 = (0, 1)$ . Then  $y_{0,2} = x_0 = (0, 1)$ , and  $y_{0,1}$  and  $y_{0,3}$  are the intersections of the line segments connecting  $x_0$  with the centers of  $\Omega_1$  and  $\Omega_3$  and the boundaries of these disks. Obviously,  $x_k = x_0$  for every  $k$ , where  $x_k$  is the sequence defined by the MM algorithm. However,  $x_0$  is not an optimal solution of the problem. In fact, the solution set is the line segment connecting  $(-1, 0)$  and  $(1, 0)$ .

Let  $\Omega$  be a nonempty closed convex set. Consider the generalized distance function  $d_F(\cdot; \Omega)$  generated by a dynamic  $F$ . For a point  $\bar{x} \notin \Omega$ , a point  $\bar{w} \in \Pi_F(\bar{x}; \Omega)$  is said to be a *representation* of the subdifferential  $\partial d_F(\bar{x}; \Omega)$  if

$$\partial \sigma_F(\bar{x} - \bar{w}) \subseteq N(\bar{w}; \Omega).$$

From the definition we see that if  $F$  is round, then  $\bar{w} = \pi_F(\bar{x}; \Omega)$  is always a representation of the subdifferential  $\partial d_F(\bar{x}; \Omega)$  for any nonempty closed convex set  $\Omega$ .

**Example 4.12** Let  $\Omega$  be the cube  $[c_1 - r, c_1 + r] \times [c_2 - r, c_2 + r] \times [c_3 - r, c_3 + r]$  of  $\mathbb{R}^3$  and let  $F$  be the closed unit ball of  $\mathbb{R}^3$  with the  $\ell^\infty$ -norm, i.e.,  $F = [-1, 1] \times [-1, 1] \times [-1, 1]$ . For any  $x \notin \Omega$ , the choice of projection

$$w := \{y \in \mathbb{R}^3 \mid y_i = \max\{c_i - r, \min\{x_i, c_i + r\}\}\} \in \pi_F(x; \Omega)$$

satisfies that condition that  $w$  is a representation of  $\partial d_F(x; \Omega)$ .

**Proposition 4.13** Consider the generalized Fermat-Torricelli problem (10) in which the distance functions are generated by a dynamics  $F$ . Let  $\{x_k\}$  be the sequence in the MM algorithm defined by

$$x_{k+1} := \arg \min \left\{ \sum_{i=1}^m \sigma_F(x - y_{k,i}) \mid x \in \Omega \right\},$$

where  $y_{k,i} \in \pi_F(x_k; \Omega_i)$ . Suppose that  $\{x_k\}$  converges to  $\bar{x}$  that does not belong to  $\Omega_i$  for  $i = 1, \dots, m$ . Suppose further that for any limit point  $\bar{y}_i \in \Pi_F(\bar{x}; \Omega_i)$  of  $\{y_{k,i}\}$ , one has that  $\bar{y}_i$  represents the subdifferential  $\partial d_F(\bar{x}; \Omega_i)$ . Then  $\bar{x}$  is an optimal solution of problem (10).

**Proof.** For sufficient large  $k$ , from the definition of the sequence  $\{x_k\}$ , one has

$$0 \in \sum_{i=1}^m \partial \sigma_F(x_{k+1} - y_{k,i}) + N(x_{k+1}; \Omega).$$

The estimate

$$\sigma_F(-y_{k,i}) \leq \sigma_F(x_k) + \sigma_F(x_k - y_{k,i}) \leq \sup_k [\sigma_F(x_k) + d_F(x_k; \Omega_i)] < \infty$$

implies that  $\{y_{k,i}\}_k$  is a bounded sequence in  $\Omega_i$  for  $i = 1, \dots, m$ . Without loss of generality, we can assume that  $y_{k,i} \rightarrow \bar{y}_i \in \pi_F(\bar{x}; \Omega_i)$  as  $k \rightarrow \infty$ . Since  $\partial p(u)$  is compact for any  $u \in \mathbb{R}^n$  and the normal cone mapping  $u \mapsto N(u; \Omega)$  has closed graph, one has

$$0 \in \sum_{i=1}^m \partial \sigma_F(\bar{x} - \bar{y}_i) + N(\bar{x}; \Omega),$$

Since  $\partial p(\bar{x} - \bar{y}_i) = \partial \sigma_F(\bar{x} - \bar{y}_i) \cap N(\bar{y}_i; \Omega_i) = \partial d_F(\bar{x}; \Omega_i)$ ,

$$0 \in \sum_{i=1}^m \partial d_F(\bar{x}; \Omega_i) + N(\bar{x}; \Omega) = \partial T(\bar{x}) + N(\bar{x}; \Omega).$$

Therefore,  $\bar{x}$  is also an optimal solution of problem (10).  $\square$

**Remark 4.14 (subgradient-type algorithms).** The generalized Fermat-Torricelli problems presented in this section and Section 3 can be solved by the projected subgradient method (see, e.g., [3, 27]). When applying the projected subgradient algorithm to the generalized Fermat-Torricelli problem (10), at iteration  $k$  we need to find a subgradient  $u_{k,i}$  of each component function  $\varphi_i(x) = d_F(x; \Omega_i)$  for  $i = 1, \dots, m$ . By the well-known *subdifferential sum rule* of convex analysis,

$$w_k := \sum_{i=1}^m u_{k,i}$$

is a subgradient of  $T$  at  $x_k$ . Proposition 4.2 as well as its specification to the case of the distance function in Corollary 4.3 provides us with a method of finding such a subgradient. Note that if  $x_k \in \Omega_i$ , the subdifferential  $\partial d_F(x_k; \Omega_i)$  always contains 0, so we can choose  $u_{k,i} = 0$ . In the case where  $x_k \notin \Omega_i$ , a subgradient  $u_{k,i}$  can be found by using a projection point  $p_{k,i} \in \Pi_F(x_k; \Omega_i)$  and find  $u_{k,i} \in \partial \sigma_F(x_k - p_{k,i}) \cap N(p_{k,i}; \Omega_i)$ .

The projected subgradient algorithm exhibits slow convergence rates when applying to the generalized Fermat-Torricelli problems (8) and (10). One of the reasons is that in each iteration, in order to get an improvement we need to calculate all subgradients  $u_{k,i}$  for  $i = 1, \dots, m$ . This is computationally expensive if the number of target sets is large. In order to overcome this shortcoming, the stochastic subgradient method provides an alternative; see [3]. The main idea is that in each iteration, rather than scanning through all the target sets to find a subgradient as in the subgradient method, we only need to choose uniformly at random one index  $t$  from  $I := \{1, \dots, m\}$ . That is, we choose  $t$  uniformly at random from  $I$ , and find the subgradient  $w_{k,t} \in \partial d_F(x_k; \Omega_t)$ . After that, we define  $\tilde{w}_k := m w_{k,t}$  and perform the iteration

$$x_{k+1} := \Pi(x_k - \alpha_k \tilde{w}_k; \Omega).$$

A more general method can be presented as follows. Fix a positive integer  $p$  such that  $p \leq |I|$ . At the iteration  $k$ , we choose uniformly at random a nonempty set of indices  $I_k$ ,  $|I_k| = p$ , that is a subset of  $I$ . Then for each  $i \in I_k$ , find  $u_{k,i} \in \partial d_F(x_k; \Omega_i)$ . After that set

$$\tilde{w}_k := m \frac{\sum_{i \in I_k} u_{k,i}}{p},$$

and perform the iteration

$$x_{k+1} := \Pi(x_k - \alpha_k \tilde{w}_k; \Omega), \quad V_{k+1} := \min\{V_k, f(x_k)\}.$$

## 5 Numerical Examples

To demonstrate the methods presented in the previous sections, let us consider a numerical examples below.

**Example 5.1** The latitude/longitude coordinates in decimal format of 1217 US cities are recorded, for example, at <http://www.realestate3d.com/gps/uslatlongdegmin.htm>. We convert the longitudes provided by the website above from positive to negative to match with the real data. Our goal is to find a point that minimizes the sum of the distances to the given points representing the cities.

If we consider the case where  $\sigma_F(x) = \|x\|$ , the Euclidean norm, Algorithm 2 allows us to find an approximate optimal value  $V^* \approx 23409.33$  and an approximate optimal solution  $x^* \approx (38.63, -97.35)$ . Similarly, if  $\sigma_F(x) = \|x\|_1$ , an approximate optimal value is  $V^* \approx 28724.68$  and an approximate optimal solution is  $x^* \approx (39.48, -97.22)$ . With the same situation but we consider the  $\ell_\infty$ -norm, an approximate optimal value is  $V^* \approx 21987.76$  and an approximate optimal solution is  $x^* \approx (37.54, -97.54)$ .

The graph below shows the relation between the number of iterations  $k$  and the optimal value  $V_k = H(y_k)$  generated by different norms.

Figure 2: Generalized Fermat-Torricelli problems with different norms

In the example below we apply Algorithm 2 in combination with the Weiszfeld's algorithm to solve generalized Fermat-Torricelli problems involving sets.

**Example 5.2** In the same setting as Example 5.1, we consider 1217 squares centered at the coordinates of the cities with the same radius (half-side length)  $r = 2$ . The constraint is the line given by the equation  $x - y = -180$ . We implement Algorithm 3 with the starting point  $x_0 = (0, 180)$  to solve the generalized Fermat-Torricelli problem generated by these squares and the Euclidean norm. In each step of the MM algorithm, we use Weiszfeld's algorithm to solve the classical Fermat-Torricelli problem generated by the projections  $y_{k,i}$  for  $i = 1, \dots, 1217$ . The MM method gives very fast convergence rate in this example. With 5 iterations of the MM algorithm along with 10 iterations of Weiszfeld's algorithm, we achieve an approximate optimal value  $V^* \approx 38161.35$  and an approximate optimal solution  $x^* \approx (56.84, -123.16)$ . It is required more than 15,000 iterations of stochastic subgradient

Figure 3: A Generalized Fermat-Torricelli Problem with US Cities

algorithm to achieve similar results. However, the MM algorithm may not converge in some situations where the sequence  $x_k$  enters the target sets, while the stochastic subgradient method is applicable to this case.

**Example 5.3** Consider six given cubes in  $\mathbb{R}^3$  with centers defined by the rows of the matrix

$$\begin{pmatrix} -6 & 6 & -4 \\ -5 & -3 & -6 \\ 2 & 3 & 4 \\ 4 & -4 & -5 \\ 5 & 6 & -6 \\ -5 & -2 & 4 \end{pmatrix}$$

and the half-side lengths are  $r_i = 1.5$  for  $i = 1, \dots, 6$ . The implementation of the algorithm above for the generalized Fermat-Torricelli problem for the cubes generated by the Euclidean norm yields a suboptimal solution  $x^* = (-1.0405, 0.8402, -1.4322)$ . This result can also be obtained by the subgradient method under much slower convergence rate.

Figure 4: A generalized Fermat-Torricelli problem with MM method

With the same problem, but we consider the  $\ell_\infty$ - norm instead of the Euclidean norm with the choice of the projection from a point  $x$  to any cube  $\Omega$  with center  $c$  and half-side length  $r$  given by

$$\{y \in \mathbb{R}^3 \mid y_i = \max\{c_i - r, \min\{x_i, c_i + r\}\}\} \in \pi_F(x; \Omega).$$

Then one obtains a suboptimal solution  $x^* = (-0.6511, 0.6511, -0.3489)$ , which can also be found by other methods.
