June 26, 2014

## Abstract

The Levenberg-Marquardt algorithm is one of the most popular algorithms for the solution of nonlinear least squares problems. Motivated by the problem structure in data assimilation, we consider in this paper the extension of the classical Levenberg-Marquardt algorithm to the scenarios where the linearized least squares subproblems are solved inexactly and/or the gradient model is noisy and accurate only within a certain probability.

Under appropriate assumptions, we show that the modified algorithm converges globally and almost surely to a first order stationary point. Our approach is applied to an instance in variational data assimilation where stochastic models of the gradient are computed by the so-called ensemble methods.

**Keywords:** Levenberg-Marquardt method, nonlinear least squares, regularization, random models, inexactness, variational data assimilation, Kalman filter/smoothed, Ensemble Kalman filter/smoothed.

## 1 Introduction

In this paper we are concerned with a class of nonlinear least squares problems for which the exact gradient is not available and replaced by a probabilistic or random model. Problems of this nature arise in several important practical contexts. One example is variational modeling for meteorology, such as 3DVAR and 4DVAR [4, 16], the dominant data assimilation least squares formulations used in weather forecasting centers worldwide. Here, ensemble methods, like those known by the abbreviations EnKF and EnKS [7, 8], are used to approximate the data arising in the solution of the corresponding linearized least squares subproblems [18], in a way where the true gradient is replaced by an approximated stochastic gradient model. Other examples appear in the broad context of derivative-free optimization problems [3] where models of the objective function evaluation may result from, a possibly random, sampling procedure [1].

The Levenberg-Marquardt algorithm [10, 12] can be seen as a regularization of the Gauss-Newton method. A regularization parameter is updated at every iteration and indirectly controls the size of the step, making Gauss Newton globally convergent (i.e., convergent to stationarity independently of the starting point). We found that the regularization term added to Gauss-Newton maintains the structure of the linearized least squares subproblems arising in data assimilation, enabling us to use techniques like ensemble methods while simultaneously providing a globally convergent approach.

However, the use of ensemble methods in data assimilation poses difficulties since it makes random approximations to the gradient. We thus propose and analyze a variant of the Levenberg-Marquardt method to deal with probabilistic gradient models. It is assumed that an approximation to the gradient is provided but only accurate with a certain probability. The knowledge of the probability of the error between the exact gradient and the model one, and in particular of its density function, can be used in our favor in the update of the regularization parameter.

Having in mind the large scale setting of applications, in particular again of data assimilation, we consider inexact the solution of the linearized least squares subproblem coming from each iteration of the Levenberg-Marquardt method. The amount of such inexactness, tolerated for global convergence, is rigorously quantified as a function of the regularization parameter, in a way that it can be used in practical implementations.

We organize this paper as follows. In Section 2, we make a short introduction to the Levenberg-Marquardt method. The new Levenberg-Marquardt method based on probabilistic gradient models is described in Section 3. Section 4 addresses the inexact solution of the linearized least squares subproblems arising in Levenberg-Marquardt. We cover essentially two possibilities: conjugate gradients and any generic inexact solution of the corresponding normal equations. The whole approach is shown to be globally convergent to first order critical points in Section 5, in the sense that a subsequence of the true objective function gradients goes to zero with probability one. The proposed approach is numerically illustrated in Section 6 with a simple problem, artificially modified to create (i) a scenario where the model gradient is a Gaussian perturbation of the exact gradient, and (ii) a scenario case where to compute the model gradient both exact/approximated gradient routines are available but the exact one (seen as expensive) is called only with a certain probability.

An application to data assimilation is presented in Section 7 where the purpose is to solve the 4DVAR problem using the methodology described in this paper. For the less familiar reader, we start by describing the 4DVAR incremental approach (Gauss-Newton) and the ways to solve the resulting linearized least squares subproblems, in particular Kalman smoother and Ensemble Kalman smoother (EnKS), the latter one leading to stochastic model gradients. We then show how our approach, namely the Levenberg-Marquardt method based on probabilistic gradient models and inexact subproblem solution, provides an appropriate framework for the application of the 4DVAR incremental approach using the EnKS method for the subproblems and finite differences for derivative approximation. Illustrative numerical results using the Lorenz 63 system as a forecast model are provided.

A discussion of conclusions and future improvements is given in Section 8. Throughout this paper  $\|\cdot\|$  will denote the vector or matrix  $\ell_2$ -norm. The notation  $[X; Y]$  will represent the concatenation of  $X$  and  $Y$  as in Matlab syntax.

## 2 The Levenberg-Marquardt method

Let us consider the following general nonlinear least squares problem

$$\min_{x \in \mathbb{R}^n} f(x) = \frac{1}{2} \|F(x)\|^2,$$

where  $F : \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a (deterministic) vector-valued function, assumed continuously differentiable, and  $m > n$ . The Gauss-Newton method is an iterative procedure where at each point  $x_j$  a step is computed as a solution of the linearized least squares subproblem

$$\min_{s \in \mathbb{R}^n} \frac{1}{2} \|F_j + J_j s\|^2,$$

where  $F_j = F(x_j)$  and  $J_j = J(x_j)$  denotes the Jacobian of  $F$  at  $x_j$ . The subproblem has a unique solution if  $J_j$  has full column rank, and in that case the step is a decent direction for  $f$ .

The Levenberg-Marquardt method [10, 12] (see also [15]) was developed to deal with the rank deficiency of  $J_j$  and to provide a globalization strategy for Gauss-Newton, and it considers a step of the form  $-(J_j^\top J_j + \gamma_j I)^{-1} J_j^\top F_j$ , corresponding to the unique solution of

$$\min_{s \in \mathbb{R}^n} m_j(x_j + s) = \frac{1}{2} \|F_j + J_j s\|^2 + \frac{1}{2} \gamma_j^2 \|s\|^2,$$

where  $\gamma_j$  is an appropriately chosen regularization parameter. Several strategies were then developed to update  $\gamma_j$ .

The Levenberg-Marquardt method can be seen as precursor of the trust-region method in the sense that it seeks to determine when the Gauss-Newton step is applicable (in which case the regularization parameter is set to zero) or when it should be replaced by a slower but safer gradient or steepest descent step (corresponding to a sufficiently large regularization parameter). The comparison with trust regions can also be drawn by looking at the square of the regularization parameter as the Lagrange multiplier of a trust-region subproblem of the form  $\min_{s \in \mathbb{R}^n} (1/2) \|F_j + J_j s\|^2$  s.t.  $\|s\| \leq \delta_j$ , and in fact it was soon suggested [13] to update the regularization parameter  $\gamma_j$  in the same form as the trust-region radius  $\delta_j$ . For this purpose, one considers the ratio between the actual reduction  $f(x_j) - f(x_j + s_j)$  attained in the objective function and the reduction  $m_j(x_j) - m_j(x_j + s_j)$  predicted by the model, given by

$$\rho_j = \frac{f(x_j) - f(x_j + s_j)}{m_j(x_j) - m_j(x_j + s_j)}.$$

Then, if  $\rho_j$  is sufficiently above zero, the step is accepted and  $\gamma_j$  is possibly decreased (corresponding to ‘ $\delta_j$  is possibly increased’). Otherwise the step is rejected and  $\gamma_j$  is increased (corresponding to ‘ $\delta_j$  is decreased’).

## 3 The Levenberg Marquardt method based on probabilistic gradient models

We are interested in the case where we do not have exact values for the Jacobian  $J_j = J(x_j)$  and the gradient  $J(x_j)^\top F(x_j)$  (of the model  $m_j(x_j + s)$  at  $s = 0$ ), but rather approximations

which we will denote by  $J_{m_j}$  and  $g_{m_j}$ . We are further interested in the case where these model approximations are built in some random fashion. We will then consider random models of the form  $M_j$  where  $g_{M_j}$  and  $J_{M_j}$  are random variables, and use the notation  $m_j = M_j(\omega_j)$ ,  $g_{m_j} = g_{M_j}(\omega_j)$ , and  $J_{m_j} = J_{M_j}(\omega_j)$  for their realizations. Note that the randomness of the models turns also random the current point  $x_j = X_j(\omega_j)$  and the current regularization parameter  $\gamma_j = \Gamma_j(\omega_j)$  generated by the corresponding optimization algorithm.

Thus, the model (where  $F_{m_j}$  represents an approximation to  $F_j$ )

$$\begin{aligned} m_j(x_j + s) - m_j(x_j) &= \frac{1}{2} \|F_{m_j} + J_{m_j}s\|^2 + \frac{1}{2} \gamma_j^2 \|s\|^2 - \frac{1}{2} \|F_{m_j}\|^2 \\ &= g_{m_j}^\top s + \frac{1}{2} s^\top \left( J_{m_j}^\top J_{m_j} + \gamma_j^2 I \right) s \end{aligned}$$

is a realization of

$$M_j(X_j + s) - M_j(X_j) = g_{M_j}^\top s + \frac{1}{2} s^\top \left( J_{M_j}^\top J_{M_j} + \Gamma_j^2 I \right) s.$$

Note that we subtracted the order zero term to the model to avoid unnecessary terminology. Our subproblem becomes then just

$$\min_{s \in \mathbb{R}^n} m_j(x_j + s) - m_j(x_j) = g_{m_j}^\top s + \frac{1}{2} s^\top \left( J_{m_j}^\top J_{m_j} + \gamma_j^2 I \right) s. \quad (1)$$

We will now impose that the gradient models  $g_{M_j}$  are accurate with a certain probability regardless of the history  $M_1, \dots, M_{j-1}$ . The accuracy is defined in terms of a multiple of the inverse of the square of regularization parameter (as it happens in [1] for trust-region methods based on probabilistic models where it is defined in terms of a multiple of the trust-region radius). As we will see later in the convergence analysis (since the regularization parameter is bounded from below), one can demand less here and consider just the inverse of a positive power of the regularization parameter.

**Assumption 3.1** *Given constants  $\alpha \in (0, 2]$ ,  $\kappa_{eg} > 0$ , and  $p \in (0, 1]$ , the sequence of random gradient models  $\{g_{M_j}\}$  is  $(p)$ -probabilistically  $\kappa_{eg}$ -first order accurate, for corresponding sequences  $\{X_j\}$ ,  $\{\Gamma_j\}$ , if the events*

$$S_j = \left\{ \|g_{M_j} - J(X_j)^\top F(X_j)\| \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \right\}$$

satisfy the following submartingale-like condition

$$p_j^* = P(S_j | \mathcal{F}_{j-1}^M) \geq p, \quad (2)$$

where  $\mathcal{F}_j^M = \sigma(M_0, \dots, M_{j-1})$  is the  $\sigma$ -algebra generated by  $M_0, \dots, M_{j-1}$ .

Correspondingly, a gradient model realization  $g_{m_j}$  is said to be  $\kappa_{eg}$ -first order accurate if

$$\|g_{m_j} - J(x_j)^\top F(x_j)\| \leq \frac{\kappa_{eg}}{\gamma_j^\alpha}.$$

The version of Levenberg-Marquardt that we will analyze and implement takes a successful step if the ratio  $\rho_j$  between actual and predicted reductions is sufficiently positive (condition  $\rho_j \geq \eta_1$  below). In such cases, and now deviating from classical Levenberg-Marquardt and following [1], the regularization parameter  $\gamma_j$  is increased if the size of the gradient model is not of the order of the inverse of  $\gamma_j$  (condition  $\|g_{m_j}\| < \eta_2/\gamma_j^2$  below). Another relevant distinction is that we necessarily decrease  $\gamma_j$  in successful iterations when  $\|g_{m_j}\| \geq \eta_2/\gamma_j^2$ . The algorithm is described below and generates a sequence of realizations for the above mentioned random variables.

**Algorithm 3.1 (Levenberg-Marquardt method based on probabilistic gradient models)**

**Initialization**

Choose the constants  $\eta_1 \in (0, 1)$ ,  $\eta_2, \gamma_{\min} > 0$ ,  $\lambda > 1$ , and  $0 < p_{\min} \leq p_{\max} < 1$ . Select  $x_0$  and  $\gamma_0 \geq \gamma_{\min}$ .

**For**  $j = 0, 1, 2, \dots$

1. Solve (or approximately solve) (1), and let  $s_j$  denote such a solution.
2. Compute  $\rho_j = \frac{f(x_j) - f(x_j + s_j)}{m_j(x_j) - m_j(x_j + s_j)}$ .
3. Make a guess  $p_j$  of the probability  $p_j^*$  given in (2) such that  $p_{\min} \leq p_j \leq p_{\max}$ .  
If  $\rho_j \geq \eta_1$ , then set  $x_{j+1} = x_j + s_j$  and

$$\gamma_{j+1} = \begin{cases} \lambda \gamma_j & \text{if } \|g_{m_j}\| < \eta_2/\gamma_j^2, \\ \max \left\{ \frac{\gamma_j}{\lambda^{1-p_j}}, \gamma_{\min} \right\} & \text{if } \|g_{m_j}\| \geq \eta_2/\gamma_j^2. \end{cases}$$

Otherwise, set  $x_{j+1} = x_j$  and  $\gamma_{j+1} = \lambda \gamma_j$ .

If exact gradients are used (in other words, if  $g_{M_j} = J(X_j)^\top F(X_j)$ ), then one always has

$$p_j^* = P \left( 0 \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \middle| \mathcal{F}_{j-1}^M \right) = 1,$$

and the update of  $\gamma$  in successful iterations reduces to  $\gamma_{j+1} = \max\{\gamma_j, \gamma_{\min}\}$  (when  $\|g_{m_j}\| \geq \eta_2/\gamma_j^2$ ), as in the more classical deterministic-type Levenberg-Marquardt methods. In general one should guess  $p_j$  based on the knowledge of the random error occurred in the application context. It is however pertinent to stress that the algorithm runs for any guess of  $p_j \in (0, 1]$  such that  $p_j \in [p_{\min}, p_{\max}]$ .

## 4 Inexact solution of the linearized least squares subproblems

Step 1 of Algorithm 3.1 requires the approximate solution of subproblem (1). As in trust-regions methods, there are different techniques to approximate the solution of this subproblem yielding a globally convergent step, and we will discuss three of them in this section. For the purposes of global convergence it is sufficient to compute a step  $s_j$  that provides a reduction in the model as good as the one produced by the so-called Cauchy step (defined as the minimizer the model along the negative gradient or steepest descent direction  $-g_{m_j}$ ).

## 4.1 A Cauchy step

The Cauchy step is defined by minimizing  $m_j(x_j - tg_{m_j})$  when  $t > 0$  and is given by

$$s_j^c = -\frac{\|g_{m_j}\|^2}{g_{m_j}^\top (J_{m_j}^\top J_{m_j} + \gamma_j^2 I) g_{m_j}} g_{m_j}. \quad (3)$$

The corresponding Cauchy decrease on the model is

$$m_j(x_j) - m_j(x_j + s_j^c) = \frac{1}{2} \frac{\|g_{m_j}\|^4}{g_{m_j}^\top (J_{m_j}^\top J_{m_j} + \gamma_j^2 I) g_{m_j}}.$$

Since  $g_{m_j}^\top (J_{m_j}^\top J_{m_j} + \gamma_j^2 I) g_{m_j} \leq \|g_{m_j}\|^2 (\|J_{m_j}\|^2 + \gamma_j^2)$ , we conclude that

$$m_j(x_j) - m_j(x_j + s_j^c) \geq \frac{1}{2} \frac{\|g_{m_j}\|^2}{\|J_{m_j}\|^2 + \gamma_j^2}.$$

The Cauchy step (3) is cheap to calculate as it does not require any system solve. Moreover, the Levenberg-Marquart method will be globally convergent if it uses a step that attains a reduction in the model as good as a multiple of the Cauchy decrease. Thus we will impose the following assumption on the step calculation:

**Assumption 4.1** *For every step  $j$  and for all realizations  $m_j$  of  $M_j$ ,*

$$m_j(x_j) - m_j(x_j + s_j) \geq \frac{\theta_{fcd}}{2} \frac{\|g_{m_j}\|^2}{\|J_{m_j}\|^2 + \gamma_j^2}$$

for some constant  $\theta_{fcd} > 0$ .

## 4.2 A truncated-CG step

Despite providing a sufficient reduction in the model and being cheap to compute, the Cauchy step is a particular form of steepest descent, which can perform poorly regardless of the step length. One can see that the Cauchy step depends on  $J_{m_j}^\top J_{m_j}$  only in the step length. Faster convergence can be expected if the matrix  $J_{m_j}^\top J_{m_j}$  influences also the step direction.

Since the Cauchy step is the first step of the conjugate gradient method when applied to the minimization of the quadratic  $m_j(x_j + s) - m_j(x_j)$ , it is natural to propose to run CG further and stop only when the residual becomes relatively small. Since CG generates iterates by minimizing the quadratic over nested Krylov subspaces, and the first subspace is the one generated by  $g_{m_j}$  (see, e.g., [14, Theorem 5.2]), the decrease attained at the first CG iteration (i.e., by the Cauchy step) is kept by the remaining.

## 4.3 A step from inexact solution of normal equations

Another possibility to approximately solve subproblem (1) is to apply some iterative solver (not necessarily CG) to the solution of the normal equations

$$(J_{m_j}^\top J_{m_j} + \gamma_j^2 I) s_j = -g_{m_j}.$$

An inexact solution  $s_j^{in}$  is then computed such that

$$\left( J_{m_j}^\top J_{m_j} + \gamma_j^2 I \right) s_j^{in} = -g_{m_j} + r_j \quad (4)$$

for a relatively small residual  $r_j$  satisfying  $\|r_j\| \leq \epsilon_j \|g_{m_j}\|$ . For such sufficiently small residuals we can guarantee Cauchy decrease.

**Assumption 4.2** For some constants  $\beta_{in} \in (0, 1)$  and  $\theta_{in} > 0$ , suppose that  $\|r_j\| \leq \epsilon_j \|g_{m_j}\|$  and

$$\epsilon_j \leq \min \left\{ \frac{\theta_{in}}{\gamma_j^\alpha}, \sqrt{\beta_{in} \frac{\gamma_j^2}{\|J_{m_j}\|^2 + \gamma_j^2}} \right\}.$$

Note that we only need the second above bound on  $\epsilon_j$  to prove the desired Cauchy decrease. The first above bound will be used later, in the convergence analysis.

**Lemma 4.1** Under Assumption 4.2, an inexact step  $s_j^{in}$  of the form (4) achieves Cauchy decrease if it satisfies Assumption 4.1 with  $\theta_{fcd} = 2(1 - \beta_{in})$ .

**Proof.** In the proof we will omit the indices  $j$ . One has

$$\begin{aligned} m(x) - m(x + s^{in}) &= -g_m^\top s^{in} - \frac{1}{2}(-g_m + r)^\top s^{in} = -\frac{1}{2}(g_m + r)^\top s^{in} \\ &= \frac{1}{2}(g_m - r)^\top (J_m^\top J_m + \gamma^2 I)^{-1}(g_m + r). \end{aligned}$$

Since  $J_m^\top J_m$  is positive semidefinite,

$$r^\top (J_m^\top J_m + \gamma^2 I)^{-1} r \leq \frac{\|r\|^2}{\gamma^2} \leq \frac{\epsilon^2 \|g_m\|^2}{\gamma^2}$$

and

$$(g_m)^\top (J_m^\top J_m + \gamma^2 I)^{-1} g_m \geq \frac{\|g_m\|^2}{\|J_m\|^2 + \gamma^2}.$$

Thus, using Assumption 4.2, we conclude that

$$\begin{aligned} m(x) - m(x + s^{in}) &\geq \left( \frac{1}{\|J_m\|^2 + \gamma^2} - \frac{\epsilon^2}{\gamma^2} \right) \|g_m\|^2 \\ &\geq \frac{2(1 - \beta_{in})}{2} \frac{\|g_m\|^2}{\|J_m\|^2 + \gamma^2}. \end{aligned}$$

■

## 5 Global convergence to first order critical points

We start by proving that two terms, that later will appear in the difference between the actual and predicted decreases, have the right order accuracy in terms of  $\gamma_j$ .

**Lemma 5.1** *For the three steps proposed (Cauchy, truncated CG, and inexact normal equations), one has that*

$$\|s_j\| \leq \frac{2\|g_{m_j}\|}{\gamma_j^2}$$

and

$$|s_j^\top(\gamma_j^2 s_j + g_{m_j})| \leq \frac{4\|J_{m_j}\|^2\|g_{m_j}\|^2 + 2\theta_{in}\|g_{m_j}\|^2}{\min\{1, \gamma_{\min}^{2-\alpha}\}\gamma_j^{2+\alpha}}.$$

(Assumption 4.2 is assumed for the inexact normal equations step  $s_j = s_j^{in}$ .)

**Proof.** We will omit the indices  $j$  again in the proof.

If  $s = s^c$  is the Cauchy point, since  $J_m^\top J_m$  is positive semidefinite,  $\|g_m^\top(J_m^\top J_m + \gamma^2 I)g_m\| \geq \gamma^2\|g_m\|^2$  and we have that  $\|s^c\| \leq \|g_m\|/\gamma^2$ . To prove the second inequality,

$$\begin{aligned} (s^c)^\top(\gamma^2(s^c) + g_m) &= \frac{\gamma^2\|g_m\|^6}{((g_m)^\top(J_m^\top J_m + \gamma^2 I)g_m)^2} - \frac{\|g_m\|^4}{(g_m)^\top(J_m^\top J_m + \gamma^2 I)g_m} \\ &= -\frac{\|g_m\|^4(g_m)^\top J_m^\top J_m g_m}{((g_m)^\top(J_m^\top J_m + \gamma^2 I)g_m)^2}, \end{aligned}$$

and then using a similar argument and  $\gamma \geq \gamma_{\min}$ ,

$$|(s^c)^\top(\gamma^2(s^c) + g_m)| \leq \frac{\|J_m\|^2\|g_m\|^2}{\gamma^4} \leq \frac{4\|J_m\|^2\|g_m\|^2 + 2\theta_{in}\|g_m\|^2}{\min\{1, \gamma_{\min}^{2-\alpha}\}\gamma^{2+\alpha}}.$$

If  $s = s^{cg}$  is obtained by truncated CG, then there exists an orthogonal matrix  $V$  with first column given by  $-g_m/\|g_m\|$  and such that

$$s^{cg} = V \left( V^\top (J_m^\top J_m + \gamma^2 I) V \right)^{-1} V^\top g_m = V \left( V^\top J_m^\top J_m V + \gamma^2 I \right)^{-1} \|g_m\| e_1,$$

where  $e_1$  is the first vector of the canonical basis of  $\mathbb{R}^n$ . From the positive semidefiniteness of  $V^\top J_m^\top J_m V$ , we immediately obtain  $\|s^{cg}\| \leq \|g_m\|/\gamma^2$ . To prove the second inequality we apply the Sherman–Morrisson–Woodbury formula, to obtain

$$s^{cg} = V \left( \frac{1}{\gamma^2} I - \frac{1}{\gamma^4} (J_m V)^\top \left( I + \frac{(J_m V)(J_m V)^\top}{\gamma^2} \right)^{-1} (J_m V) \right) \|g_m\| e_1.$$

Since  $V e_1 = -g_m/\|g_m\|$ ,

$$\gamma^2 s^{cg} + g_m = -\frac{1}{\gamma^2} V (J_m V)^\top \left( I + \frac{(J_m V)(J_m V)^\top}{\gamma^2} \right)^{-1} (J_m V) \|g_m\| e_1.$$

Now, from the fact that  $(J_m V)(J_m V)^\top/\gamma^2$  is positive semidefinite, the norm of the inverse of  $I + (J_m V)(J_m V)^\top/\gamma^2$  is no greater than one, and thus (since  $V$  is orthogonal)

$$\|\gamma^2 s^{cg} + g_m\| \leq \frac{\|J_m\|^2\|g_m\|}{\gamma^2}.$$

Finally (recalling  $\gamma \geq \gamma_{\min}$ ),

$$\begin{aligned} |(s^{cg})^\top(\gamma^2(s^{cg}) + g_m)| &\leq \|s^{cg}\| \|\gamma^2 s^{cg} + g_m\| \leq \frac{\|J_m\|^2 \|g_m\|^2}{\gamma^4} \\ &\leq \frac{4\|J_m\|^2 \|g_m\|^2 + 2\theta_{in} \|g_m\|^2}{\min\{1, \gamma_{\min}^{2-\alpha}\} \gamma^{2+\alpha}}. \end{aligned}$$

If  $s = s^{in}$  is an inexact solution of the normal equations, and the residual satisfies Assumption 4.2,  $\|s^{in}\| \leq (\|g_m\| + \|r\|)/\gamma^2 \leq 2\|g_m\|/\gamma^2$ . Applying the Sherman–Morrisson–Woodbury formula

$$s^{in} = \left( \frac{1}{\gamma^2} I - \frac{1}{\gamma^4} J_m^\top \left( I + \frac{J_m J_m^\top}{\gamma^2} \right)^{-1} J_m \right) (-g_m + r).$$

Thus,

$$\gamma^2 s^{in} + g_m = -\frac{1}{\gamma^2} J_m^\top \left( I + \frac{J_m J_m^\top}{\gamma^2} \right)^{-1} J_m (-g_m + r) + r,$$

Using the fact that the norm of the inverse above is no greater than one, Assumption 4.2, and  $\gamma \geq \gamma_{\min}$ ,

$$\begin{aligned} |(s^{in})^\top(\gamma^2(s^{in}) + g_m)| &\leq \|s^{in}\| \|\gamma^2 s^{in} + g_m\| \\ &\leq \frac{4\|J_m\|^2 \|g_m\|^2}{\gamma^4} + \frac{2\theta_{in} \|g_m\|^2}{\gamma^{2+\alpha}} \\ &\leq \frac{4\|J_m\|^2 \|g_m\|^2 + 2\theta_{in} \|g_m\|^2}{\min\{1, \gamma_{\min}^{2-\alpha}\} \gamma^{2+\alpha}}. \end{aligned}$$

■

We proceed by stating the conditions required for global convergence.

**Assumption 5.1** *The function  $f$  is continuously differentiable in an open set containing  $L(x_0) = \{x \in \mathbb{R}^n : f(x) \leq f(x_0)\}$  with Lipschitz continuous gradient on  $L(x_0)$  and corresponding constant  $\nu > 0$ .*

*The Jacobian model is uniformly bounded, i.e., there exists  $\kappa_{J_m} > 0$  such that  $\|J_{m_j}\| \leq \kappa_{J_m}$  for all  $j$ .*

The next result is a classical one and essentially says that the actual and predicted reductions match each other well for a value of the regularization parameter  $\gamma_j$  sufficiently large relative to the size of the gradient model (which would correspond to say for a sufficiently small trust-region radius in trust-region methods).

**Lemma 5.2** *Let Assumption 5.1 hold. Let also Assumption 4.2 hold for the inexact normal equations step  $s_j = s_j^{in}$ . If  $x_j$  is not a critical point of  $f$  and the gradient model  $g_{m_j}$  is  $\kappa_{eg}$ -first order accurate, and if*

$$\gamma_j \geq \left( \frac{\kappa_j}{1 - \eta_1} \right)^{\frac{1}{\alpha}} \quad \text{with} \quad \kappa_j = \left( 1 + \frac{\kappa_{J_m}^2}{\gamma_{\min}^2} \right) \frac{2\nu + \frac{2\kappa_{eg}}{\|g_{m_j}\|} + 2\theta_{in} + 8\kappa_{J_m}^2}{\min\{1, \gamma_{\min}^{2-\alpha}\} \theta_{fcd}},$$

then  $\rho_j \geq \eta_1$ .

**Proof.** Again we omit the indices  $j$  in the proof. Making a Taylor expansion,

$$\begin{aligned}
1 - \frac{\rho}{2} &= \frac{m(x) - f(x) + f(x+s) - m(x+s) + m(x) - m(x+s)}{2[m(x) - m(x+s)]} \\
&= \frac{s^\top J(x)^\top F(x) + R - s^\top g_m - s^\top (J_m^\top J_m + \gamma^2 I)s - s^\top g_m}{2[m(x) - m(x+s)]} \\
&= \frac{R + (J(x)^\top F(x) - g_m)^\top s - s^\top (J_m^\top J_m)s - s^\top (\gamma^2 s + g_m)}{2[m(x) - m(x+s)]},
\end{aligned}$$

where  $R \leq \nu \|s\|^2/2$ .

Now, using Lemma 5.1, Assumptions 4.1 and 5.1, and  $\gamma \geq \gamma_{\min}$ ,

$$\begin{aligned}
1 - \frac{\rho}{2} &\leq \frac{\frac{\nu}{2} \|s\|^2 + \frac{\kappa_{eg}}{\gamma^\alpha} \|s\| + \|J_m\|^2 \|s\|^2 - s^\top (\gamma^2 s + g)}{\frac{\theta_{fcd} \|g_m\|^2}{\|J_m\|^2 + \gamma^2}} \\
&\leq \frac{\frac{2\nu \|g_m\|^2}{\gamma^4} + \frac{2\kappa_{eg} \|g_m\|}{\gamma^{2+\alpha}} + \frac{4\kappa_{J_m}^2 \|g_m\|^2}{\gamma^4} + \frac{4\kappa_{J_m}^2 \|g_m\|^2 + 2\|g_m\|^2 \theta_{in}}{\min\{1, \gamma_{\min}^{2-\alpha}\} \gamma^{2+\alpha}}}{\frac{\theta_{fcd} \|g_m\|^2}{\gamma^2 (\|J_m\|^2 / \gamma_{\min}^2 + 1)}} \\
&\leq \frac{\left(1 + \frac{\kappa_{J_m}}{\gamma_{\min}^2}\right) \left(2\nu + \frac{2\kappa_{eg}}{\|g_m\|} + 2\theta_{in} + 8\kappa_{J_m}^2\right)}{\min\{1, \gamma_{\min}^{2-\alpha}\} \theta_{fcd} \gamma^\alpha} \leq \frac{\kappa}{\gamma^\alpha} \leq 1 - \eta_1.
\end{aligned}$$

We have thus proved that  $\rho \geq 2\eta_1 > \eta_1$ . ■

One now establishes that the regularization parameter goes to infinity, which corresponds to say in [1] that the trust-region radius goes to zero.

**Lemma 5.3** *Let the second part of Assumption 5.1 hold (the uniform bound on  $J_{m_j}$ ). For every realization of the Algorithm 3.1,  $\lim_{j \rightarrow \infty} \gamma_j = \infty$ .*

**Proof.** If the result is not true, then there exists a bound  $B > 0$  such that the number of times that  $\gamma_j < B$  happens is infinite. Because of the way  $\gamma_j$  is updated one must have an infinity of iterations such  $\gamma_{j+1} \leq \gamma_j$ , and for these iterations one has  $\rho_j \geq \eta_1$  and  $\|g_{m_j}\| \geq \eta_2/B^2$ . Thus,

$$\begin{aligned}
f(x_j) - f(x_j + s_j) &\geq \eta_1 [m_j(x_j) - m_j(x_j + s_j)] \\
&\geq \eta_1 \left( \frac{\theta_{fcd}}{2} \frac{1}{\|J_m\|^2 + \gamma^2} \right) \|g_{m_j}\|^2 \\
&\geq \frac{\eta_1 \theta_{fcd}}{2(\kappa_{J_m}^2 + B^2)} \left( \frac{\eta_2}{B^2} \right)^2.
\end{aligned}$$

Since  $f$  is bounded from below by zero, the number of such iterations can not be infinite, and hence we arrived at a contradiction. ■

Now, if we assume that the gradient models are  $(p_j)$ -probabilistically  $\kappa_{eg}$ -first order accurate, we can show our main global convergence result. First we will state an auxiliary result from the literature that will be useful for the analysis (see [5, Theorem 5.3.1] and [5, Exercise 5.3.1]).

**Lemma 5.4** Let  $G_j$  be a submartingale, in other words, a set of random variables which are integrable ( $E(|G_j|) < \infty$ ) and satisfy  $E(G_j|\mathcal{F}_{j-1}) \geq G_{j-1}$ , for every  $j$ , where  $\mathcal{F}_{j-1} = \sigma(G_0, \dots, G_{j-1})$  is the  $\sigma$ -algebra generated by  $G_0, \dots, G_{j-1}$  and  $E(G_j|\mathcal{F}_{j-1})$  denotes the conditional expectation of  $G_j$  given the past history of events  $\mathcal{F}_{j-1}$ .

Assume further that there exists  $M > 0$  such that  $|G_j - G_{j-1}| \leq M < \infty$ , for every  $j$ . Consider the random events  $C = \{\lim_{j \rightarrow \infty} G_j \text{ exists and is finite}\}$  and  $D = \{\limsup_{j \rightarrow \infty} G_j = \infty\}$ . Then  $P(C \cup D) = 1$ .

**Theorem 5.1** Let Assumption 5.1 hold. Let also Assumption 4.2 hold for the inexact normal equations step  $s_j = s_j^{in}$ .

Suppose that the gradient model sequence  $\{g_{M_j}\}$  is  $(p_j)$ -probabilistically  $\kappa_{eg}$ -first order accurate for some positive constant  $\kappa_{eg}$  (Assumption 3.1). Let  $\{X_j\}$  be a sequence of random iterates generated by Algorithm 3.1. Then almost surely,

$$\liminf_{j \rightarrow \infty} \|\nabla f(X_j)\| = 0.$$

**Proof.** The proof follows the same lines as [1, Theorem 4.2]. Let

$$W_j = \sum_{i=0}^j \left( \frac{1}{p_i} 1_{S_i} - 1 \right),$$

where  $S_i$  is as in Assumption 3.1. Recalling  $p_j^* = P(S_j|\mathcal{F}_{j-1}^M) \geq p_j$ , we start by showing that  $\{W_j\}$  is a submartingale:

$$E(W_j|\mathcal{F}_{j-1}^M) = W_{j-1} + \frac{1}{p_j} P(S_j|\mathcal{F}_{j-1}^M) - 1 \geq W_{j-1}.$$

Moreover,  $\min\{1, 1/p_j - 1\} \leq |W_j - W_{j-1}| \leq \max\{(1 - p_j)/p_j, 1\} \leq \max\{1/p_j, 1\} = 1/p_j$ . Since  $0 < p_{\min} \leq p_j \leq p_{\max} < 1$ , one has  $0 < \min\{1, 1/p_{\max} - 1\} \leq |W_j - W_{j-1}| \leq 1/p_{\min}$ . Thus, from  $0 < \min\{1, 1/p_{\max} - 1\} \leq |W_j - W_{j-1}|$ , the event  $\{\lim_{j \rightarrow \infty} W_j \text{ exists and is finite}\}$  has probability zero, and using Lemma 5.4 and  $|W_j - W_{j-1}| \leq 1/p_{\min}$ , one concludes that  $P(\limsup_{j \rightarrow \infty} W_j = \infty) = 1$ .

Suppose there exist  $\epsilon > 0$  and  $j_1$  such that, with positive probability,  $\|\nabla f(X_j)\| \geq \epsilon$  for all  $j \geq j_1$ . Let now  $\{x_j\}$  and  $\{\gamma_j\}$  be any realization of  $\{X_j\}$  and  $\{\Gamma_j\}$ , respectively, built by Algorithm 3.1. By Lemma 5.3, there exists  $j_2$  such that  $\forall j \geq j_2$

$$\gamma_j > b_\epsilon = \max \left\{ \left( \frac{2\kappa_{eg}}{\epsilon} \right)^{\frac{1}{\alpha}}, \left( \frac{2\eta_2}{\epsilon} \right)^{\frac{1}{2}}, \lambda^{\frac{p-1}{p}} \gamma_{\min}, \left( \frac{\kappa_\epsilon}{1 - \eta_1} \right)^{\frac{1}{\alpha}} \right\} \quad (5)$$

where

$$\kappa_\epsilon = \left( 1 + \frac{\kappa_{Jm}^2}{\gamma_{\min}^2} \right) \frac{2\nu + \frac{4\kappa_{eg}}{\epsilon} + 2\theta_{in} + 8\kappa_{Jm}^2}{\min\{1, \gamma_{\min}^{2-\alpha}\} \theta_{fcd}}.$$

For any  $j \geq j_0 = \max\{j_1, j_2\}$  two cases are possible.

If  $1_{S_j} = 1$ , then, from (5),

$$\|g_{m_j} - J(x_j)^\top F(x_j)\| \leq \frac{\kappa_{eg}}{\gamma_j^\alpha} < \frac{\epsilon}{2},$$

yielding  $\|g_{m_j}\| \geq \epsilon/2$ . From (5) we also have that  $\|g_{m_j}\| \geq \epsilon/2 \geq \eta_2/\gamma_j^2$ . On the other hand, Lemma 5.2, (5), and  $\|g_{m_j}\| \geq \epsilon/2$  together imply that  $\rho_j \geq \eta_1$ . Hence, from this and Step 3 of Algorithm 3.1, the iteration is successful. Also, from  $\|g_{m_j}\| \geq \eta_2/\gamma_j^2$  and (5) (note that  $(1-x)/x$  is decreasing in  $(0, 1]$ ),  $\gamma$  is updated in Step 3 as

$$\gamma_{j+1} = \frac{\gamma_j}{\lambda \frac{1-p_j}{p_j}}.$$

Let now  $B_j$  be a random variable with realization  $b_j = \log_\lambda(b_\epsilon/\gamma_j)$ . In the case  $1_{S_j} = 1$ ,

$$b_{j+1} = b_j + \frac{1-p_j}{p_j}.$$

If  $1_{S_j} = 0$ , then  $b_{j+1} \geq b_j - 1$ , because either  $\gamma_{j+1} \leq \gamma_j$  therefore  $b_{j+1} \geq b_j$  or  $\gamma_{j+1} = \lambda\gamma_j$  therefore  $b_{j+1} \geq b_j - 1$ . Hence  $B_j - B_{j_0} \geq W_j - W_{j_0}$ , and from  $P(\limsup_{j \rightarrow \infty} W_j = \infty) = 1$  one obtains  $P(\limsup_{j \rightarrow \infty} B_j = \infty) = 1$  which leads to a contradiction with the fact that  $B_j < 0$  happens for all  $j \geq j_0$  with positive probability. ■

## 6 A numerical illustration

The main concern in the application of Algorithm 3.1 is to ensure that the gradient model is  $(p_j)$ -probabilistically accurate (i.e.,  $p_j^* \geq p_j$ , see Assumption 3.1) or at least to find a lower bound  $p_{\min} > 0$  such that  $p_j^* \geq p_{\min}$ . However, one can, in some situations, overcome these difficulties such as in the cases where the model gradient (i) is a Gaussian perturbation of the exact one, or (ii) results from using either the exact one (seen as expensive) or an approximation. In the former case we will consider a run of the algorithm under a stopping criterion of the form  $\gamma_j > \gamma_{\max}$ .

### 6.1 Gaussian noise

At each iteration of the algorithm, we consider an artificial random gradient model, by adding to the exact gradient an independent Gaussian noise, more precisely we have  $g_{M_j} = J(X_j)^\top \nabla F(X_j) + \varepsilon_j$  where  $(\varepsilon_j)_i \sim N(0, \sigma_{j,i}^2)$ , for  $i = 1, \dots, n$ . Let  $\Sigma_j$  be a diagonal matrix with diagonal elements  $\sigma_{j,i}$ ,  $i = 1, \dots, n$ . It is known that

$$\|\Sigma_j \varepsilon_j\|^2 = \sum_{i=1}^n \left( \frac{(\varepsilon_j)_i}{\sigma_{j,i}} \right)^2 \sim \chi_2(n),$$

where  $\chi_2(n)$  is the chi-2 distribution with  $n$  degrees of freedom. To be able to give an explicit form of the probability of the model being  $\kappa_{eg}$ -first order accurate, for a chosen  $\kappa_{eg} > 0$ , we assume also that the components of the noise are identically distributed, that is  $\sigma_{j,i} = \sigma_j$ ,  $\forall i \in \{1, \dots, n\}$ . Because of the way in which  $\gamma_j$  is updated in Algorithm 3.1, it is bounded by  $\lambda^j \gamma_0$ , and thus  $\Gamma_j \leq \min\{\lambda^j \gamma_0, \gamma_{\max}\}$ , where  $\gamma_{\max}$  is the constant used in the stopping criterion. One therefore has

$$\begin{aligned} p_j^* &= P \left( \|g_{M_j} - J(X_j)^\top \nabla F(X_j)\| \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \middle| F_{j-1}^M \right) \\ &\geq P \left( \|\Sigma_j \varepsilon_j\|^2 \leq \left( \frac{\kappa_{eg}}{\sigma_j \min\{\lambda^j \gamma_0, \gamma_{\max}\}^\alpha} \right)^2 \middle| F_{j-1}^M \right). \end{aligned}$$

run number	1	2	3
$\ (x, y) - (x^*, y^*)\ /\ (x^*, y^*)\  (p_j = 1)$	1.0168	0.3833	0.7521
$f(x, y) (p_j = 1)$	0.5295	0.0368	1.47
$\ (x, y) - (x^*, y^*)\ /\ (x^*, y^*)\  (p_j = \tilde{p}_j)$	0.0033	0.0028	0.0147
$f(x, y) (p_j = \tilde{p}_j)$	2.6474e-006	1.9778e-006	4.3548e-005
$\ (x, y) - (x^*, y^*)\ /\ (x^*, y^*)\  (p_j = p_{\min})$	0.1290	0.1567	0.0068
$f(x, y) (p_j = p_{\min})$	0.0036	0.0059	9.1426e-006

Table 1: For three different runs of Algorithm 3.1, the table shows the values of the objective function and relative error of the solution found for the three choices  $p_j = 1$ ,  $p_j = \tilde{p}_j$ , and  $p_j = p_{\min} = 5 \cdot 10^{-3}$ .

Using the Gaussian nature of the noise  $\varepsilon_j$  and the fact that it is independent from the filtration  $F_{j-1}^M$ , we obtain

$$p_j^* \geq CDF_{\chi^2(n)}^{-1} \left( \left( \frac{\kappa_{eg}}{\sigma_j \min\{\lambda^j \gamma_0, \gamma_{\max}\}^\alpha} \right)^2 \right) \stackrel{\text{def}}{=} \tilde{p}_j. \quad (6)$$

where  $CDF_{\chi^2(n)}$  is the cumulative density function of a chi-squared distribution with  $n$  degrees of freedom.

The numerical illustration was done with the following nonlinear least squares problem defined using the well-known Rosenbrock function

$$f(x, y) = \frac{1}{2} (\|x - 1\|^2 + 100\|y - x^2\|^2) = \frac{1}{2} \|F(x, y)\|^2.$$

The minimizer of this problem is  $(x^*, y^*)^\top = (1, 1)^\top$ .

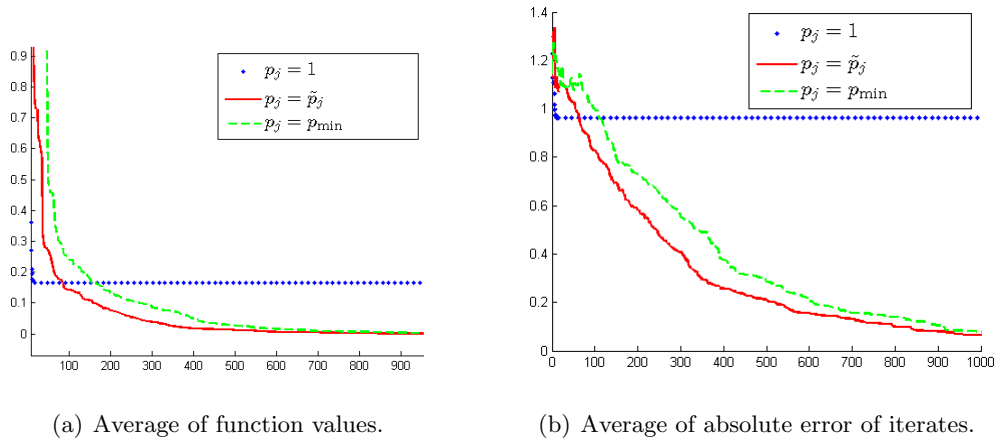

Algorithm 3.1 was initialized with  $x_0 = (1.2, 0)^\top$  and  $\gamma_0 = 1$ . The algorithmic parameters were set to  $\eta_1 = \eta_2 = 10^{-3}$ ,  $\gamma_{\min} = 10^{-6}$ , and  $\lambda = 2$ . The stopping criterion used is  $\gamma_j > \gamma_{\max}$  where  $\gamma_{\max} = 10^6$ . We used  $\alpha = 1/2$ ,  $\sigma_j = \sigma = 10 \forall j$ , and  $\kappa_{eg} = 100$  for the random gradient model.

Figure 1 depicts the average, over 60 runs of Algorithm 3.1, of the objective function values, the absolute errors of the iterates, and the percentages of successful iterations, using, across all iterations, the three choices  $p_j = 1$ ,  $p_j = \tilde{p}_j$ , and  $p_j = p_{\min}$ . In the last case,  $p_{\min}$  is an underestimation of  $p_j^*$  given by

$$p_{\min} = CDF_{\chi^2(n)}^{-1} \left( \left( \frac{\kappa_{eg}}{\sigma \gamma_{\max}^\alpha} \right)^2 \right) = 5 \cdot 10^{-3}.$$

The final objective function values and the relative final errors are shown in Table 1 for the first three runs of the algorithm. One can see that the use of  $p_j = \tilde{p}_j$  leads to a better performance than  $p_j = p_{\min}$  (because  $\tilde{p}_j \geq p_{\min}$  is a better bound for  $p_j^*$  than  $p_{\min}$  is).

In the case where  $p_j = 1$ , Algorithm 3.1 exhibits a performance worse than for the two other choices of  $p_j$ . The algorithm stagnated after some iterations, and could not approximate the minimizer with a descent accuracy. In this case,  $\gamma_j$  is increasing along the iterations, and thus it becomes very large after some iterations while the step  $s_j \sim 1/\gamma_j^2$  becomes very small.

(a) Average of function values.

(b) Average of absolute error of iterates.

(c) Average percentage of successful iterations.

Figure 1: Average results of Algorithm 3.1 for 60 runs when using probabilities  $p_j = 1$  (dotted line),  $p_j = \tilde{p}_j$  (solid line), and  $p_j = p_{\min}$  (dashed line).

Other numerical experiments (not reported here) have shown that, when the error on the gradient is small ( $\sigma \ll 1$ ), the two versions  $p_j = \tilde{p}_j$  and  $p_j = 1$  give almost the same results, and this is consistent with the theory because when  $\sigma \rightarrow 0$ , from (6),

$$\tilde{p}_j \rightarrow CDF_{\chi_2(n)}^{-1}(\infty) = 1.$$

Note that, on the other extreme, when the error on the gradient is big ( $\sigma \gg 1$ ), version  $p_j = \tilde{p}_j$  approaches version  $p_j = p_{\min}$  since  $\tilde{p}_j \simeq p_{\min}$ .

## 6.2 Expensive gradient case

Let us assume that, in practice, for a given problem, one has two routines for gradient calculation. The first routine computes the exact gradient and is expensive. The second routine is less expensive but computes only an approximation of the gradient. The model gradient results from a call to either routine. In this section, we propose a technique to choose the probability of calling the exact gradient which makes our approach applicable.

**Algorithm 6.1 (Algorithm to determine when to call the exact gradient  $g_{M_j}$ )**

**Initialization**

Choose the constant  $p_{\min} \in (0, 1)$  ( $p_{\min}$  is the lower bound of all the probabilities  $p_j^*$ ).

**For a chosen probability  $\bar{p}_j$  such that  $\bar{p}_j \geq p_{\min}$**

1. Sample a random variable  $U \sim \mathcal{U}([0, 1/\bar{p}_j])$ , independently from  $F_{j-1}^M$ , and  $\mathcal{U}([0, 1/\bar{p}_j])$  is the uniform distribution on the interval  $[0, 1/\bar{p}_j]$ .
  - 1.1 If  $U \leq 1$ , compute  $g_{M_j}$  using the routine which gives the exact gradient.
  - 1.2 Otherwise, compute  $g_{M_j}$  using the routine which gives an approximation of the exact gradient.

**Lemma 6.1** *If we use Algorithm 6.1 to compute the model gradient at the  $j$ -th iteration of Algorithm 3.1, then we have  $p_j^* \geq \bar{p}_j \geq p_{\min}$ .*

**Proof.** By using inclusion of events, we have that

$$\begin{aligned} p_j^* &= P \left( \|g_{M_j} - J(X_j)^\top F(X_j)\| \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \middle| F_{j-1}^M \right) \\ &\geq P \left( \|g_{M_j} - J(X_j)^\top F(X_j)\| = 0 \middle| F_{j-1}^M \right) \end{aligned}$$

and from Algorithm 6.1 we conclude that

$$P \left( \|g_{M_j} - J(X_j)^\top F(X_j)\| = 0 \middle| F_{j-1}^M \right) \geq P(U \leq 1) = \frac{1}{1/\bar{p}_j},$$

and thus  $p_j^* \geq \bar{p}_j$ . The other inequality,  $\bar{p}_j \geq p_{\min}$ , is imposed in the algorithm. ■

For the experiments we use the same test function and the same parameters as in Section 6.1. In Step 1.2 of Algorithm 6.1, we set the model gradient  $g_{M_j}$  to the exact gradient of the function plus a Gaussian noise sampled from  $N(0, 10I)$ . Across all iterations, we use Algorithm 6.1 to compute  $g_{M_j}$  with the three following choices of  $\bar{p}_j$ :

- $\bar{p}_j = 1/10$ , i.e., at iteration  $j$  the model gradient coincides with the exact gradient with probability at least  $\bar{p}_j = 1/10$ . Moreover, we have  $p_j^* \geq \tilde{p}_j$ , where  $\tilde{p}_j$  is the same as in (6), and thus one can choose  $p_j = \max\{1/10, \tilde{p}_j\}$ .
- $\bar{p}_j = 1/50$ , with the same analysis as before and one can choose  $p_j = \max\{1/50, \tilde{p}_j\}$ .
- $\bar{p}_j \simeq 0$  ( $\bar{p}_j = 10^{-10}$  in the experiment below), i.e., at iteration  $j$  the probability that the model gradient coincides with the exact gradient is very small. Thus one can choose  $p_j = \tilde{p}_j$ .

Figure 2 depicts the average of the function values and the absolute error of the iterates over 60 runs of Algorithm 3.1 when using the three choices of the probability  $p_j$ . As expected, the better the quality of the model is the more efficient the Algorithm 3.1 is (less iterations are needed to ‘converge’ in the sense of sufficiently reducing the objective function value and absolute error). We can clearly see that Algorithm 3.1 using the models for which  $p_j = \max\{1/10, \tilde{p}_j\}$  provides a better approximation to the minimizer of the objective function than using the models for which  $p_j = \max\{1/50, \tilde{p}_j\}$ , and this latter one is better than the case when  $p_j = \tilde{p}_j$ .

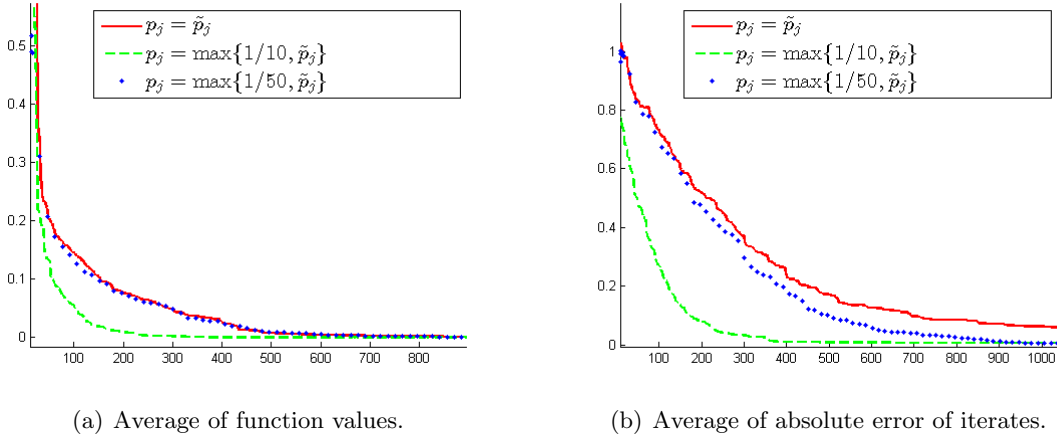

Figure 2: Average results of Algorithm 3.1 for 60 runs when using probabilities  $p_j = \tilde{p}_j$  (solid line),  $p_j = \max\{1/10, \tilde{p}_j\}$  (dotted line), and  $p_j = \max\{1/50, \tilde{p}_j\}$  (dashed line).

## 7 Application to data assimilation

Data assimilation is the process by which observations of a real system are incorporated into a computer model (the forecast) to produce an estimate (the analysis) of the state of system. 4DVAR is the data assimilation method mostly used in weather forecasting centers worldwide. 4DVAR attempts to reconcile a numerical model and the observations, by solving a very large weighted nonlinear least squares problem. The unknown is a vector of system states over discrete points in time. The objective function to be minimized is the sum of the squares of the differences between the initial state and a known background state at the initial time and the differences between the actual observations and ones predicted by the model.

### 7.1 4DVAR problem

We want to determine  $x_0, \dots, x_T$ , where  $x_i$  is an estimator of the state  $X_i$  at time  $i$ , from the background state  $X_0 = x_b + W_b$ ,  $W_b \sim N(0, B)$ . The observations are denoted by  $y_i = \mathcal{H}_i(X_i) + V_i$ ,  $V_i \sim N(0, R_i)$ ,  $i = 0, \dots, T$ , and the numerical model by  $X_i = \mathcal{M}_i(X_{i-1}) + W_i$ ,  $W_i \sim N(0, Q_i)$ ,  $i = 1, \dots, T$ , where  $\mathcal{M}_i$  is the model operator at time  $i$  and  $\mathcal{H}_i$  is the observation operator at time  $i$  (both not necessary linear). The random vectors  $W_b$ ,  $V_i$ ,  $W_i$  are the noises on the background, on the observation at time  $i$ , and on the model at time  $i$ , respectively, and are supposed to be Gaussian distributed with mean zero and covariance matrices  $B$ ,  $R_i$ , and  $Q_i$ , respectively. Assuming that the errors (the background, the observation, and the model errors) are independent among each other and uncorrelated in time [6], the posterior probability function of this system (in other words, the pdf of  $X_0, \dots, X_T$  knowing  $y_0, \dots, y_T$ ) is proportional to

$$\exp^{-\frac{1}{2} \left( \|x_0 - x_b\|_{B^{-1}}^2 + \sum_{i=1}^T \|x_i - \mathcal{M}_i(x_{i-1})\|_{Q_i^{-1}}^2 + \sum_{i=0}^T \|y_i - \mathcal{H}_i(x_i)\|_{R_i^{-1}}^2 \right)}$$

and therefore the maximizer of the posterior probability function estimator is defined to be the minimizer of the weak constraint 4DVAR problem [16] defined by:

$$\min_{x_0, \dots, x_T \in \mathbb{R}^n} \frac{1}{2} \left( \|x_0 - x_b\|_{B^{-1}}^2 + \sum_{i=1}^T \|x_i - \mathcal{M}_i(x_{i-1})\|_{Q_i^{-1}}^2 + \sum_{i=0}^T \|y_i - \mathcal{H}_i(x_i)\|_{R_i^{-1}}^2 \right). \quad (7)$$

## 7.2 Incremental 4DVAR

To find the solution of the nonlinear least squares problem (7), one proceeds iteratively by linearization. At each iteration, one solves the auxiliary linear least squares problem for the increments  $\delta x_0, \dots, \delta x_T$

$$\min_{\delta x_0, \dots, \delta x_T \in \mathbb{R}^n} \frac{1}{2} \left( \|x_0 + \delta x_0 - x_b\|_{B^{-1}}^2 + \sum_{i=1}^T \|x_i + \delta x_i - \mathcal{M}_i(x_{i-1}) - \mathcal{M}'_i(x_{i-1})\delta x_{i-1}\|_{Q_i^{-1}}^2 + \sum_{i=0}^T \|y_i - \mathcal{H}_i(x_i) - \mathcal{H}'_i(x_i)\delta x_i\|_{R_i^{-1}}^2 \right). \quad (8)$$

Such an iterative process is nothing else than the Gauss-Newton method [2] for nonlinear least squares, known in the data assimilation community as the incremental approach [4].

Denote  $z_i = \delta x_i$ ,  $z_b = x_b - x_0$ ,  $z = [z_0; \dots; z_T]$ ,  $m_i = \mathcal{M}_i(x_{i-1}) - x_i$ ,  $d_i = y_i - \mathcal{H}_i(x_i)$ ,  $M_i = \mathcal{M}'_i(x_{i-1})$ , and  $H_i = \mathcal{H}'_i(x_i)$ . Then (8) becomes

$$\min_{z \in \mathbb{R}^{n(T+1)}} \frac{1}{2} \left( \|z_0 - z_b\|_{B^{-1}}^2 + \sum_{i=1}^T \|z_i - M_i z_{i-1} - m_i\|_{Q_i^{-1}}^2 + \sum_{i=0}^T \|d_i - H_i z_i\|_{R_i^{-1}}^2 \right). \quad (9)$$

It is known that the solution of the linear least squares problem (9) is exactly the same as the Kalman smoother estimator for the following linear system (see [17])

$$Z_0 = z_b + W_b, \quad W_b \sim N(0, B), \quad (10)$$

$$Z_i = M_i Z_{i-1} + m_i + W_i, \quad W_i \sim N(0, Q_i), \quad i = 1, \dots, T, \quad (11)$$

$$d_i = H_i Z_i + V_i, \quad V_i \sim N(0, R_i), \quad i = 0, \dots, T. \quad (12)$$

For simplicity, we now rewrite the linear system (10)–(12) as:

$$Z = Z_b + W, \quad W \sim N(0, B_W), \quad (13)$$

$$D = HZ + V, \quad V \sim N(0, R), \quad (14)$$

where

$$\begin{aligned} Z &= [Z_0; \dots; Z_T] \text{ is the joint state of the states } Z_0, \dots, Z_T, \\ D &= [d_0; d_1; \dots; d_T], \\ Z_b &= [z_b; M_1 z_b + m_1; M_2(M_1 z_b + m_1) + m_2; \dots; M_T(\dots M_1 z_b + m_1 \dots) + m_T], \\ H &= \text{diag}(H_0, \dots, H_T) \text{ is the joint observation operator,} \\ W &= [W_b; M_1 W_b + W_1; M_2(M_1 W_b + W_1) + W_2; \dots; M_T(\dots M_1 W_b + W_1 \dots) + W_T], \\ B_W &= \text{cov}(W), \quad V = [V_0; V_1; \dots; V_T], \quad \text{and } R = \text{cov}(V). \end{aligned}$$

To simplify it even more, we make the change of variables  $U = Z - Z_b$ , and then (13)–(14) becomes

$$\begin{aligned} U &\sim N(0, B_W) \\ D - HZ_b &= HU + V, \quad V \sim N(0, R), \end{aligned}$$

and the linear least squares problem (9) becomes (with  $z$  replaced by  $u + Z_b$ )

$$\min_{u \in \mathbb{R}^{n(T+1)}} \frac{1}{2} \left( \|u\|_{B_W^{-1}}^2 + \|D - HZ_b - Hu\|_{R^{-1}}^2 \right). \quad (15)$$

To solve problem (15), we propose to use the ensemble Kalman smoother as a linear least squares solver instead of the Kalman smoother. The ensemble approach is naturally parallelizable over the ensemble members. Moreover, the proposed approach uses finite differences from the ensemble, and no tangent or adjoint operators are needed (i.e., the method is free of derivatives).

### 7.3 Kalman and ensemble Kalman smoothers

The Kalman smoother gives the expectation and the covariance of the state  $U$  (equivalently  $Z$ ) knowing the data  $D$ , in other words it calculates  $U^a = E(U|D)$  and  $P^a = \text{cov}(U|D)$ , and is described by

$$\begin{aligned} U^a &= K(D - HZ_b), \\ P^a &= (I - KH)B_W, \\ K &= B_W H^\top (HB_W H^\top + R)^{-1}. \end{aligned}$$

For  $Z$  one has  $Z^a = E(Z|D) = Z_b + K(D - HZ_b)$ . In the data assimilation community, the vector  $U^a$  (equivalently  $Z^a$ ) is called the analysis and the matrix  $K$  is called the Kalman gain.

The Ensemble Kalman Smoother (EnKS) [6, 7] consists of applying Monte Carlo to generate an ensemble following  $N(0, B_W)$  and then use its corresponding empirical covariance matrix instead of  $B_W$  to approximate  $U^a$ . Let us denote by  $k$  the ensemble members index, running over  $k = 1, \dots, N$ , where  $N$  is the ensemble size. We sample an ensemble  $\tilde{U}^k$  from  $N(0, B_W)$  by first sampling  $w_b^k$  according to  $N(0, B)$ ,  $w_1^k$  according to  $N(0, Q_1)$ ,  $\dots$ ,  $w_T^k$  according to  $N(0, Q_T)$ , and then by setting  $\tilde{U}^k$  as follows:  $\tilde{U}_0^k = w_b^k$ ,  $\tilde{U}_1^k = M_1 w_b^k + w_1^k$ ,  $\dots$ ,  $\tilde{U}_T^k = M_T(\dots M_1 w_b^k + w_1^k \dots) + w_T^k$ . Let  $\tilde{U}^k = [\tilde{U}_0^k; \tilde{U}_1^k; \dots; \tilde{U}_T^k]$  and

$$\bar{\tilde{U}} = \frac{1}{N} \sum_{k=1}^N \tilde{U}^k \quad \text{and} \quad B^N = \frac{1}{N-1} \sum_{k=1}^N (\tilde{U}^k - \bar{\tilde{U}})(\tilde{U}^k - \bar{\tilde{U}})^\top$$

be the empirical mean and covariance of the ensemble  $\tilde{U}^k$ , respectively. One has

$$B^N = CC^\top, \quad \text{where} \quad C = \frac{1}{\sqrt{N-1}} [\tilde{U}^1 - \bar{\tilde{U}}, \tilde{U}^2 - \bar{\tilde{U}}, \dots, \tilde{U}^N - \bar{\tilde{U}}].$$

We then build the centered ensemble  $U^k = \tilde{U}^k - \bar{\tilde{U}}$ . Note that the empirical mean of the ensemble  $U^k$  is equal to zero and that its empirical covariance matrix is  $B^N$ .

Now one generates the ensemble  $U^{k,a}$  as follows

$$U^{k,a} = U^k + K^N(D - HZ_b - V^k), \quad (16)$$

where  $V^k$  is sampled from  $N(0, R)$ , and

$$K^N = B^N H^\top (HB^N H^\top + R)^{-1}.$$

In practice, the empirical covariance matrix  $B^N$  is never computed or stored since to compute the matrix products  $B^N H^\top$  and  $HB^N H^\top$  only matrix-vector products are needed:

$$\begin{aligned} B^N H^\top &= \frac{1}{N-1} \sum_{k=1}^N U^k U^{k\top} H^\top = \frac{1}{N-1} \sum_{k=1}^N U^k h_k^\top, \\ HB^N H^\top &= H \frac{1}{N-1} \sum_{k=1}^N U^k U^{k\top} H^\top = \frac{1}{N-1} \sum_{k=1}^N h_k h_k^\top, \\ K^N &= \frac{1}{N-1} \sum_{k=1}^N U^k h_k^\top \left( \frac{1}{N-1} \sum_{k=1}^N h_k h_k^\top + R \right)^{-1}, \end{aligned}$$

where  $h_k = HU^k = [H_0 U_0^k; \dots; H_T U_T^k]$ .

We denote by  $\bar{U}^a$  and  $\bar{V}$  the empirical mean of the ensembles  $U^{k,a}$  and  $V^k$ , respectively. One has from (16)

$$\bar{U}^a = K^N(D - HZ_b - \bar{V}). \quad (17)$$

It is known that when  $N \rightarrow \infty$ ,  $\bar{U}^a \rightarrow U^a$  in  $L^p$  (see [9, 11]), and thus, asymptotically,  $\bar{U}^a$  is the solution of the linearized subproblem (15) (and  $\bar{U}^a + Z_b$  is the solution of the linearized subproblem (9)).

#### 7.4 The linearized least squares subproblems arising in EnKS

From (17) we conclude that  $\bar{U}^a$  is the Kalman smoother estimator for the following system

$$\begin{aligned} \tilde{U} &\sim N(0, B^N), \\ \tilde{D} &= H\tilde{U} + \tilde{V}, \quad \tilde{V} \sim N(0, R), \quad \text{where } \tilde{D} = D - HZ_b - \bar{V}. \end{aligned} \quad (18)$$

Hence, for a large  $N$  (such that  $B^N$  is invertible),  $\bar{U}^a$  is the solution of the following linear least squares problem

$$\min_{u \in \mathbb{R}^{n(T+1)}} \frac{1}{2} \left( \|u\|_{(B^N)^{-1}}^2 + \|Hu - \tilde{D}\|_{R^{-1}}^2 \right). \quad (19)$$

From the above derivation, we conclude that when we use the EnKS (until now with exact derivatives) to approximate the solution of the linearized subproblem (9), what is obtained is the solution of the linear least squares problem (19). The least squares model in (19) can be seen, in turn, as a realization of the following stochastic model,

$$\frac{1}{2} \left( \|u\|_{B^{-1}}^2 + \|Hu - \tilde{D}\|_{R^{-1}}^2 \right), \quad (20)$$

where  $\mathcal{B}^{-1}$  and  $\tilde{\mathcal{D}}$  are random variables, with realizations  $(B^N)^{-1}$  and  $\tilde{D}$ , respectively.

Both the incremental method and the method which approximates the solution of the linearized subproblem (9) using EnKS may diverge. Convergence to a stationary point of (7) can be recovered by controlling the size of the step, and one possibility to do so is to consider the application of the Levenberg-Marquardt method as in Algorithm 3.1. At each step, a regularization term is then added to the model in (19)

$$m(x+u) = \frac{1}{2} \left( \|u\|_{(B^N)^{-1}}^2 + \|Hu - \tilde{D}\|_{R^{-1}}^2 + \gamma^2 \|u\|^2 \right), \quad (21)$$

which corresponds to adding a regularization term to the model (20)

$$M(x+u) = \frac{1}{2} \left( \|u\|_{\mathcal{B}^{-1}}^2 + \|Hu - \tilde{\mathcal{D}}\|_{R^{-1}}^2 + \Gamma^2 \|u\|^2 \right). \quad (22)$$

We now provide the details about the solution of (21). For this purpose let

$$P^N = (I - K^N H) B^N.$$

Note that by using the Sherman–Morrison–Woodbury formula one has

$$P^N = ((B^N)^{-1} + H^T R^{-1} H)^{-1},$$

in other words,  $P^N$  is the inverse of the Hessian of model in (19).

**Proposition 7.1** *The minimizer of the model (21) is  $u^* = \bar{U}^a - P^N (P^N + (1/\gamma^2)I_n)^{-1} \bar{U}^a$ .*

**Proof.** Since  $\bar{U}^a$  is the solution of problem (19), a Taylor expansion around  $\bar{U}^a$  of the model in (19) gives

$$\frac{1}{2} \left( \|u\|_{(B^N)^{-1}}^2 + \|Hu - \tilde{D}\|_{R^{-1}}^2 \right) = \frac{1}{2} \left( \|\bar{U}^a\|_{(B^N)^{-1}}^2 + \|H\bar{U}^a - \tilde{D}\|_{R^{-1}}^2 + \|u - \bar{U}^a\|_{(P^N)^{-1}}^2 \right).$$

Hence, the minimizer of the model (21) is the same as the minimizer of

$$\frac{1}{2} \left( \|\bar{U}^a\|_{(B^N)^{-1}}^2 + \|H\bar{U}^a - \tilde{D}\|_{R^{-1}}^2 + \|u - \bar{U}^a\|_{(P^N)^{-1}}^2 + \gamma^2 \|u\|^2 \right).$$

and thus given by

$$u^* = ((P^N)^{-1} + \gamma^2 I)^{-1} (P^N)^{-1} \bar{U}^a. \quad (23)$$

By using the Sherman–Morrison–Woodbury formula, one has

$$((P^N)^{-1} + \gamma^2 I)^{-1} = P^N - P^N (P^N + (1/\gamma^2)I_n)^{-1} P^N,$$

which together with (23) concludes the proof. ■

## 7.5 Derivative-free LM-EnKS

The linearized model and observation operators appear only when acting on a given vector, and therefore they could be efficiently approximated by finite differences. The linearized observation operator  $H_i = \mathcal{H}'_i(x_i)$  appears in the action on the ensemble members and can be approximated by

$$H_i \delta x_i = \mathcal{H}'_i(x_i) \delta x_i \simeq \frac{\mathcal{H}_i(x_i + \tau \delta x_i) - \mathcal{H}_i(x_i)}{\tau},$$

where  $\tau > 0$  is a finite differences parameter. Originally, in EnKS, to avoid the derivatives of  $\mathcal{H}_i$ , the quantity  $H_i \delta x_i = \mathcal{H}_i(x_i + \delta x_i) - \mathcal{H}_i(x_i)$  is approximated by  $\mathcal{H}_i(x_i + \delta x_i) - \mathcal{H}_i(x_i)$ , which is equivalent to do finite differences with the parameter  $\tau = 1$ . The linearized model  $M_1 = \mathcal{M}'_1(x_0)$  occurs in the action on the vector  $z_b$ ,  $M_2 = \mathcal{M}'_2(x_1)$  occurs in the action on the vector  $M_1 z_b$ , and so on for  $M_3, \dots, M_T$ , and (just for the first two terms) the finite difference approximations are

$$\begin{aligned} M_1 z_b &= \mathcal{M}'_1(x_0) z_b \simeq \frac{\mathcal{M}_1(x_0 + \tau z_b) - \mathcal{M}_1(x_0)}{\tau} \\ M_2(M_1 z_b + m_1) &= \mathcal{M}'_2(x_1)(M_1 z_b + m_1) \simeq \frac{\mathcal{M}_2(x_1 + \tau(M_1 z_b + m_1)) - \mathcal{M}_2(x_1)}{\tau} \\ &\simeq \frac{\mathcal{M}_2(x_1 + \mathcal{M}_1(x_0 + \tau z_b) - \mathcal{M}_1(x_0) + \tau m_1) - \mathcal{M}_2(x_1)}{\tau}. \end{aligned}$$

Since our approach is derivative free, we replace all the derivatives of the model and of the observation operators by approximation by finite differences. The quantities using derivatives become then

$$\begin{aligned} \hat{h}_k &= \left[ \frac{\mathcal{H}_0(x_0 + \tau U_0^k) - \mathcal{H}_0(x_0)}{\tau}; \dots; \frac{\mathcal{H}_T(x_T + \tau U_T^k) - \mathcal{H}_T(x_T)}{\tau} \right] \simeq h_k, \\ \hat{K}^N &= \frac{1}{N-1} \sum_{k=1}^N U^k \hat{h}_k^\top \left( \frac{1}{N-1} \sum_{k=1}^N \hat{h}_k \hat{h}_k^\top + R \right)^{-1} \simeq K^N, \\ \hat{Z}_b &= \left[ z_b; \frac{\mathcal{M}_1(x_0 + \tau z_b) - \mathcal{M}_1(x_0)}{\tau} + m_1; \dots \right] \simeq Z_b, \\ \hat{H} Z_b &= \left[ \frac{\mathcal{H}_0(x_0 + \tau z_b) - \mathcal{H}_0(x_0)}{\tau}; \dots \right] \simeq H Z_b, \\ \hat{U}^a &= \hat{K}^N (D - \hat{H} Z_b - \bar{V}) \simeq \bar{U}^a, \\ \hat{P}^N &= B^N - \hat{K}^N \frac{1}{N-1} \sum_{k=1}^N \hat{h}_k U^k \top \simeq P^N, \\ \hat{u}^* &= \hat{U}^a - \hat{P}^N \left( \hat{P}^N + (1/\gamma^2) I_n \right)^{-1} \hat{U}^a \simeq u^*. \end{aligned} \tag{24}$$

Since  $\hat{u}^*$  is an approximation to  $u^*$  using finite differences for derivatives, there exists a constant  $M > 0$ , which depends on the second derivatives of the model and observation operators, such that  $\|e\| \leq M\tau$ , where  $e = u^* - \hat{u}^*$ . Moreover, from (21),  $u^*$  is the solution of the normal equations

$$\left( (B^N)^{-1} + H^T R^{-1} H + \gamma^2 I \right) u^* = H^T R^{-1} \tilde{D},$$

where  $H^T R^{-1} \tilde{D} = \nabla m(x) = g_m$ , and thus

$$\left( (B^N)^{-1} + H^T R^{-1} H + \gamma^2 I \right) \hat{u}^* = g_m - \left( (B^N)^{-1} + H^T R^{-1} H + \gamma^2 I \right) e,$$

and so  $\hat{u}^*$  can be seen as an inexact solution of the normal equations, with a residual equal to

$$r = - \left( (B^N)^{-1} + H^T R^{-1} H + \gamma^2 I \right) e.$$

We have seen that the solution of the normal equations can be inexact as long as Assumption 4.2 is met. The residual  $r$  is then required to satisfy  $\|r\| \leq \epsilon \|g_m\|$ , for some  $\epsilon > 0$ , to fulfill the global convergence requirements of our Levenberg-Marquardt approach, and for this purpose we need the following assumption.

**Assumption 7.1** *The approximation  $\hat{u}^*$  of  $u^*$  satisfies  $\|e\| \leq M\tau$ , where  $e = u^* - \hat{u}^*$ , for some constant  $M > 0$ .*

*The Jacobian of the observation operator  $\mathcal{H}$  is uniformly bounded, i.e., there exists  $\kappa_H > 0$  such that  $\|\mathcal{H}'_i(x_i)\| \leq \kappa_H$  for all  $i \in \{0, \dots, T\}$  and for all iterations  $j$ .*

We note that the iteration index  $j$  has been omitted from the notation of this section until now. In fact, the point  $x$  has been denoting the iterate  $x_j$ .

**Proposition 7.2** *Under Assumption 7.1, if the finite differences parameter  $\tau$  is such that*

$$\tau \leq \frac{\epsilon \|g_m\|}{M \left( \|(B^N)^{-1}\| + \kappa_H^2 \|R^{-1}\| + \gamma^2 \right)}, \quad (26)$$

then  $\|r\| \leq \epsilon \|g_m\|$ .

**Proof.** One has

$$\begin{aligned} \|r\| &\leq \left\| (B^N)^{-1} + H^T R^{-1} H + \gamma^2 I \right\| \|e\| \\ &\leq \left( \|(B^N)^{-1}\| + \kappa_H^2 \|R^{-1}\| + \gamma^2 \right) M\tau \leq \epsilon \|g_m\|. \end{aligned}$$

■

Now, from (22) the gradient of the stochastic model is  $g_{M_j} = -H^T R^{-1} \tilde{D}$  and from (15) the exact gradient of the function to minimized in problem (7) is  $-H^T R^{-1} (D - HZ_b)$ . Thus,

$$p_j^* = P \left( \left\| H^T R^{-1} (D - HZ_b - \tilde{D}) \right\| \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \middle| \mathcal{F}_{j-1}^{\tilde{M}} \right).$$

But we know that  $D - HZ_b - \tilde{D} = \bar{V} = (1/N) \sum_{i=1}^N V_i$ , where  $V_i$  are i.i.d. and follow  $N(0, R)$ , and thus  $D - HZ_b - \tilde{D} \sim N(0, R/N)$  and  $R^{-1} (D - HZ_b - \tilde{D}) \sim \frac{R^{-1/2}}{\sqrt{N}} N(0, I)$ . Thus

$$\begin{aligned} p_j^* &\geq P \left( \frac{\kappa_H \|R^{-1/2}\|}{\sqrt{N}} \|N(0, I)\| \leq \frac{\kappa_{eg}}{\Gamma_j^\alpha} \middle| \mathcal{F}_{j-1}^{\tilde{M}} \right) \\ &= P \left( \|N(0, I)\| \leq \frac{\kappa \sqrt{N}}{\Gamma_j^\alpha} \middle| \mathcal{F}_{j-1}^{\tilde{M}} \right), \end{aligned}$$

where  $\kappa = \frac{\kappa_{eg}}{\kappa_H \|R^{-1/2}\|}$ . Since  $\Gamma_j \leq \min\{\lambda^j \gamma_0, \gamma_{\max}\}$ ,

$$p_j^* \geq CDF_{\chi_2(m)}^{-1} \left( \left( \frac{\kappa \sqrt{N}}{\min\{\lambda^j \gamma_0, \gamma_{\max}\}^\alpha} \right)^2 \right) \stackrel{\text{def}}{=} \tilde{p}_j, \quad (27)$$

where  $m = \sum_{i=0}^T m_i$ ,  $m_i$  is the size of  $y_i$ , and  $\gamma_{\max}$  is the tolerance used in the stopping criterion. Note that  $\lim_{N \rightarrow \infty} \tilde{p}_j = 1$ , thus  $\lim_{N \rightarrow \infty} p_j^* = 1$ , and hence when  $N \rightarrow \infty$  the gradient approximation using ensemble converges almost surely to the exact gradient.

We are now ready to propose a version of Algorithm 3.1 for the solution of the 4DVAR problem (7) when using EnKS as the linear solver.

### Algorithm 7.1 (Levenberg-Marquardt method based on probabilistic gradient models for data assimilation)

#### Initialization

Choose the constants  $\eta_1 \in (0, 1)$ ,  $\eta_2, \gamma_{\min}, \gamma_{\max} > 0$ , and  $\lambda > 1$ . Select  $x_0$  and  $\gamma_0 \in [\gamma_{\min}, \gamma_{\max}]$ . Choose all the parameters related to solving the 4DVAR problem (7) using EnKS as the linear solver.

**For**  $j = 0, 1, 2, \dots$  **and while**  $\gamma_j \leq \gamma_{\max}$

1. Let  $x = x_j$ . Choose  $\tau$  satisfying (26). Compute the increment  $\hat{u}^*$  using (25) and set  $z^* = \hat{u}^* + \hat{Z}_b$ , where  $\hat{Z}_b$  is computed as in (24). Let  $s_j = z^*$ .
2. Compute  $\rho_j = \frac{f(x_j) - f(x_j + s_j)}{m_j(x_j) - m_j(x_j + s_j)}$ , where  $f$  is the nonlinear least squares model in (7) and  $m_j$  is the model (21).
3. If  $\rho_j \geq \eta_1$ , then set  $x_{j+1} = x_j + s_j$  and

$$\gamma_{j+1} = \begin{cases} \lambda \gamma_j & \text{if } \|g_{m_j}\| < \eta_2 / \gamma_j^2, \\ \max \left\{ \frac{\gamma_j}{\lambda^{-p_j}}, \gamma_{\min} \right\} & \text{if } \|g_{m_j}\| \geq \eta_2 / \gamma_j^2, \end{cases}$$

where  $p_j = \tilde{p}_j$  is computed as in (27).

Otherwise, set  $x_{j+1} = x_j$  and  $\gamma_{j+1} = \lambda \gamma_j$ .

## 7.6 Computational experiments with Lorenz 63 as model

To evaluate the performance of Algorithm 7.1 for data assimilation, we will test it using the classical twin experiment technique used in the data assimilation community. This technique consists on fixing an initial true state (denoted by  $\text{truth}_0$ ) and then to integrate it over time using the model to obtain the true state at each time  $i$  (denoted by  $\text{truth}_i$ ). We then build the data  $y_i$  by applying the observation operator  $\mathcal{H}_i$  to the truth at time  $i$  and by adding a Gaussian perturbation  $N(0, R_i)$ . Similarly, the background  $x_b$  is sampled from the Gaussian distribution with mean  $\text{truth}_0$  and covariance matrix  $B$ . Then we try to recover the truth using the observations and the background.

We consider as model in the 4DVAR problem (7), the Lorenz 63 equations, a simple dynamical model with chaotic behavior. The Lorenz equations are given by the nonlinear system

$$\frac{dx}{dt} = -\sigma(x - y), \quad \frac{dy}{dt} = \rho x - y - xz, \quad \text{and} \quad \frac{dz}{dt} = xy - \beta z,$$

where  $x = x(t)$ ,  $y = y(t)$ ,  $z = z(t)$ , and  $\sigma$ ,  $\rho$ ,  $\beta$  are parameters. The state at time  $t$  is  $X_t = (x(t), y(t), z(t))^\top \in \mathbb{R}^3$ . This nonlinear system is discretized using a fourth-order Runge-Kutta method. The parameters  $\sigma$ ,  $\rho$ ,  $\beta$  are chosen as 10, 28, and  $8/3$  respectively. The initial truth is set to  $(1, 1, 1)^\top$  and the truth at time  $i$  to  $\text{truth}_i = \mathcal{M}(\text{truth}_{i-1}) + W_i$ , where  $W_i$  is sampled from  $N(0, Q_i)$  and  $\mathcal{M}$  is the model obtained by discretization of the Lorenz 63 system. The model error covariance is given by  $Q_i = \sigma_q^2 I$  where  $\sigma_q = 10^{-4}$ . The background mean  $x_b$  is sampled from  $N(\text{truth}_0, B)$ . The background covariance is  $B = \sigma_b^2 I$ , where  $\sigma_b = 1$ . The time step is chosen as  $dt = 0.11 > 0.1$  which renders the model more nonlinear. The time windows length is  $T = 40$ . The observation operator is  $\mathcal{H}_i = 10I$ . At each time  $i$ , the observations are constructed as follows:  $y_i = \mathcal{H}_i(\text{truth}_i) + V_i$ , where  $V_i$  is sampled from  $N(0, R)$ ,  $R = \sigma_r^2 I$ , and  $\sigma_r = 1$ .

The size of the ensemble used is  $N = 400$ . Following the spirit of Proposition 4.2, the finite difference parameter is set as

$$\tau_j = \min \left\{ 10^{-3}, \frac{\epsilon_j \|g_{m_j}\|}{M \left( \|(B^N)^{-1}\| + \kappa_H^2 \|R^{-1}\| + \gamma_j^2 \right)} \right\},$$

where the value of 1 is chosen for the unknown constants  $M$  and  $\kappa_H$  (see Assumption 7.1). In this experimental framework, the model gradient is given by  $g_{m_j} = -H^\top R^{-1} \tilde{D} = 10\tilde{D}$ , where  $\tilde{D}$  is computed according to (18). Then, following the spirit of Assumption 4.2,  $\epsilon_j$  is chosen as

$$\epsilon_j = \min \left\{ \frac{\theta_{in}}{\gamma_j^\alpha}, \sqrt{\beta_{in} \frac{\gamma_j^2}{\kappa_{Jm}^2 + \gamma_j^2}} \right\},$$

where  $\beta_{in} = 1/2$ ,  $\theta_{in} = 1$ , and  $\alpha = 0.5$ . The unknown constant  $\kappa_{Jm}$  (see Assumption 5.1) is set to 1.

The basic algorithmic parameters are set to  $\eta_1 = \eta_2 = 10^{-6}$ ,  $\gamma_{\min} = 10^{-5}$ ,  $\gamma_{\max} = 10^6$ , and  $\lambda = 8$ . The initial regularization parameter is  $\gamma_0 = 1$ . Finally, we set  $\kappa = 1$  in the calculation of  $\tilde{p}_j$  given in (27).

In order to measure the quality of the solutions we use as performance metric the Root Mean Square Error (RMSE), which is defined as follows:

$$\text{RMSE} = \frac{1}{T} \sum_{i=0}^T \text{RSE}_i,$$

where  $i$  is the time index,  $T$  is the number of time steps, and  $\text{RSE}_i$  is the Root Squares Error at time  $i$  given by

$$\text{RSE}_i = \sqrt{\frac{1}{n} (\text{truth}_i - x_i)^\top (\text{truth}_i - x_i)},$$

where  $\text{truth}_i$  is the true vector state at time  $i$  and  $x_i$  is the estimator of the state computed using the algorithm.

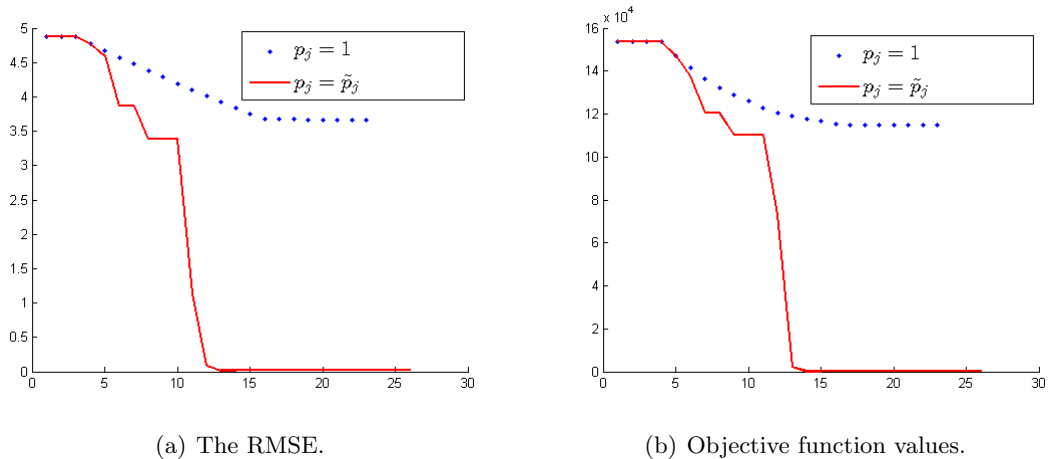

Figure 3: Results of one run of Algorithm 7.1 when using probabilities  $p_j = 1$  (dotted line) and  $p_j = \tilde{p}_j$  (solid line).

Figures 3(a) and 3(b) show, respectively, the RMSE and the objective function values, for one run of Algorithm 7.1, using the choices  $p_j = \tilde{p}_j$  and  $p_j = 1$ . (One run shows well the behavior of the algorithm on this problem and there was no need to take averages over several runs.) Algorithm 7.1 using  $p_j = \tilde{p}_j$  took 35 iterations to reduce the RMSE from 4.88 to 0.019. But when  $p_j = 1$  is used, the same 35 iterations were not enough to drive the RMSE to the same value. These results illustrate the importance of using probability  $p_j = \tilde{p}_j$  to update the regularization parameter  $\gamma$ .

## 8 Conclusions

In this paper we have adapted the Levenberg-Marquardt method for nonlinear least-squares problems to handle the cases where the gradient of the objective function is subject to noise or only computed accurately within a certain probability. The gradient model was then considered random in the sense of being a realization of a random variable, and assumed first order accurate under some probability  $p_j^*$  (see (2)). Given the knowledge of a lower bound  $p_j$  for this probability (see Assumption 3.1), we have shown how to update the regularization parameter of the method in such a way that the whole approach is almost surely globally convergent. The analysis followed similar steps as in the theory in [1]. The main difficulty in the application of Algorithm 3.1 is to ensure that the models are indeed  $(p_j)$ -probabilistically accurate, but we presented a number of practical situations where this is achievable.

The last section of the paper was devoted to the well known 4DVAR problem in data assimilation. We have shown that in the framework of the application of the Levenberg-Marquardt method, when using the Ensemble Kalman smoother (EnKS) method for the formulation and solution of the corresponding linearized least squares subproblems, it can also be provided a lower bound for the probability of first order accuracy, which renders our approach applicable and sound.

We have covered also the situation where the linearized least squares problems arising in the Levenberg-Marquardt method are solved inexactly, which then encompasses a range of practical

situations, from inexactness in linear algebra to inexactness in derivatives. This is particularly useful in the 4DVAR application to accommodate finite differences of the nonlinear operators involved.

A number of issues need further and deeper investigation, in particular the study of the performance of our approach when applied to large and realistic data assimilation problems.
