

ERROR ESTIMATES FOR THE EULER DISCRETIZATION OF AN OPTIMAL CONTROL PROBLEM WITH FIRST-ORDER STATE CONSTRAINTS*

J. FRÉDÉRIC BONNANS[†] AND ADRIANO FESTA[‡]

Abstract. We study the error introduced in the solution of an optimal control problem with first order state constraints, for which the trajectories are approximated with a classical Euler scheme.

We obtain order one approximation results in the L^∞ norm (as opposed to the order $2/3$ obtained in the literature). We assume either a strong second order optimality condition, or a weaker one in the case where the state constraint is scalar, satisfies some hypotheses for junction points, and the time step is constant.

Our technique is based on some homotopy path of discrete optimal control problems that we study using perturbation analysis of nonlinear programming problems.

Key words. Optimal control, nonlinear systems, state constraints, Euler discretization, rate of convergence.

AMS subject classifications. 49M25, 65L10, 65L70, 65K10.

1. Introduction, discussion of literature. Numerical methods for the resolution of an optimal control problem are based on a finite dimensional approximation, generally obtained through a discretization of the trajectory and a piecewise constant or polynomial control. Obtaining error estimates for such approximations is obviously an important issue.

The first works related appeared in the 1970s; they dealt with convergence of a discrete optimal control solution (see e.g. [9], [10], and [21]). Other results of convergence, provided with modern variational techniques, are also [25]; a survey of the results in this area is [11].

In this paper we will focus on the case of *pure* state constraints, a case which presents some special difficulties. In particular it is known that when the constraint qualification (see [14]) holds and the Lagrangian verifies a local condition of coercivity, the discrete problem obtained with an Euler scheme has a solution, for a sufficiently fine mesh, and the corresponding Lagrange multipliers are at distance $O(\bar{h})$, in the L^2 norm, where \bar{h} is the maximal discretization step, from the continuous solution/multiplier. This important result is due to [13].

The choice of the norm is a delicate point: through the Legendre-Clebsch condition we can get typically an estimation for our variables in a L^2 norm which settles badly with the pure state constrained problem. Such problem naturally requires estimations in the L^∞ norm. This is the so called “*two-norm discrepancy*” [20].

Another sensible matter is that the cost function does not necessarily have derivatives in L^2 . This suggests to work in a non linear space of Lipschitz continuous functions with bounded Lipschitz constants. In this setting the L^2 convergence implies L^∞ convergence. This is the way proposed in [13] to obtain a convergence result in the L^∞ norm. In such work the error bound, of order $O(\bar{h}^{2/3})$ (where \bar{h} denotes the largest time step), is as highlighted by the same authors through an empirical *a posteriori* test not tight.

We assume either a strong second order optimality condition, and a variable time step (as it was done in [13] with a constant time step), or a weaker request in the case where the state constraint is scalar, the problem satisfies some hypotheses for junction points and the time step is constant.

In this second case our hypotheses can be motivated in the following way. They allow to obtain the stability of the extremals (of the continuous problem) under a small perturbation, see [4]. We obtain a similar result for the discretized problem. By contrast, for a vector state constraint we are not aware of such stability results, even in the continuous case. This suggests that it might be not easy to obtain the stability of the extremals after discretization without a strong second order optimality condition. This is an interesting open question that we leave for future work, as well as the case of higher order state constraints.

1.1. Structure of the paper. In Section 2 we introduce the problem and the assumptions adopted in the paper, and we state our main result (Theorem 2.5), i.e., a $O(\bar{h})$ error estimate for the control, state, costate and multiplier. The homotopy path is introduced in Section 3. The path starts with $\theta = 1$, the associated solution being provided by a sample of the continuous problem. It involves the control, state, costate and multiplier denoted by $X^\theta := (u^\theta, y^\theta, p^\theta, \eta^\theta)$, and by the definition is such that $\|X^\theta - X^1\|_\infty \leq \varepsilon$. For $\theta = 0$ we reach a local solution of the discretized problem. The smoothness of its solution is established in Section 4. In Section 5 we check that, under appropriate hypotheses, in a neighbourhood of X^1 , X^θ has a directional derivatives δX^θ whose L^∞ norm is of order \bar{h} . More precisely, due to some coercivity properties of the Hessian of the Lagrangian, we first obtain $O(\bar{h})$ estimates in the L^2 norm for the directional derivatives of u^θ and η^θ , from which the $O(\bar{h})$ estimates in the L^∞ norm for y^θ and p^θ easily follow. Then using the fact that the state constraint is of first order, we derive the $O(\bar{h})$ estimates in the L^∞ norm for u^θ and η^θ . Section 6 is dedicated to a simple numerical test. The example, taken from [15], was also used in [13]. The numerical results are in accordance with our theoretical result and they confirms the tightness of the estimate. An appendix is devoted to the analysis of hypothesis **(A5)**.

2. The continuous problem and its discretization. We consider the following pure state constrained optimal control problem

$$(\mathcal{P}) \left\{ \begin{array}{l} \text{Minimize } \phi(y(T)); \\ \dot{y}(t) = f(u(t), y(t)), \quad \text{for a.a. } t \in [0, T]; \\ y(0) = y_0; \\ g_i(y(t)) \leq 0, \end{array} \right\} \quad \text{subject to} \quad \begin{array}{l} \\ \\ \\ t \in [0, T], \quad i = 1, \dots, r, \end{array} \quad (2.1)$$

where the control $u(t)$ and the state $y(t)$ belong to the spaces $\mathcal{U} := L^\infty(0, T; \mathbb{R}^m)$ and $\mathcal{Y} := W^{1, \infty}(0, T; \mathbb{R}^n)$, resp., and g_i is the i th component of the vector g . Moreover we assume:

- (A0)** The mappings $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$, $f : \mathbb{R}^m \times \mathbb{R}^n \rightarrow \mathbb{R}^n$, and $g : \mathbb{R}^n \rightarrow \mathbb{R}^r$ are of class C^2 with locally Lipschitz second order continuous derivatives. Additionally, $g_i(y_0) < 0$ for every $i = 1, \dots, r$.

A *trajectory* of (\mathcal{P}) is an element (u, y) of $\mathcal{U} \times \mathcal{Y}$ solution of the state equation (2.1). We say that (\tilde{u}, \tilde{y}) is a *local solution* of (\mathcal{P}) , if it minimizes $\phi(\cdot)$ over the set of feasible trajectories (u, y) satisfying $\|u - \tilde{u}\|_\infty \leq \delta$ for some $\delta > 0$. We assume that

- (A1)** The trajectory (\bar{u}, \bar{y}) is a local solution of (\mathcal{P}) in $\mathcal{U} \times \mathcal{Y}$, and \bar{u} is a continuous function of time.

The *first order time derivative* of the state constraint is the function

$$g^{(1)} : \mathbb{R}^m \times \mathbb{R}^n \rightarrow \mathbb{R}^r, (u, y) \rightarrow g'(y)f(u, y). \quad (2.2)$$

Note that $g^{(1)}(\bar{u}, \bar{y})$ is the time derivative of $g(\bar{y})$ along a trajectory.

Denote by $\mathcal{A}(t) := \{i = 1, \dots, r \mid g_i(\bar{y}(t)) = 0\}$ the set of active constraints at time t . We say that the trajectory (\bar{u}, \bar{y}) has *regular first order state constraints* if the following holds:

(A2) There exists $\alpha > 0$ such that, for any $\lambda \in \mathbb{R}^{r*}$ verifying $\lambda_i = 0$ if $i \notin \mathcal{A}(t)$, the following holds:

$$|\lambda| \leq \alpha_g \left| \sum_{i \in \mathcal{A}(t)} \lambda_i \nabla_u g_i^{(1)}(\bar{u}, \bar{y}) \right|, \quad \forall t \in [0, T].$$

The *Hamiltonian* function $H : \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^{n*} \rightarrow \mathbb{R}$ is defined by:

$$H[p](u, y) := pf(u, y).$$

With this classical notation we view the Hamiltonian as a function of (u, y) , parameterized by p .

We define the *contact set* by

$$I_i := \{t \in [0, T]; g_i(\bar{y}(t)) = 0\}, \quad i \in \{1, \dots, r\}.$$

We say also that the i -constraint is *active* at time t , if $t \in I_i$; otherwise the constraint will be *inactive*. A maximal open interval (a, b) of I_i (resp. of $[0, T] \setminus I_i$) is called *boundary arc* (resp. *interior arc*). The left and right endpoints of a boundary arc are called *entry* and *exit* points, respectively. We call *junction points* the union of entry and exit points.

2.1. Optimality conditions. We identify the measure space $\mathcal{M}[0, T]$ with functions of $BV([0, T])$ with value 0 at time T . We recall here the classical definition of regular Pontryagin extremal.

DEFINITION 2.1. *A trajectory (\bar{u}, \bar{y}) is a regular Pontryagin extremal of (\mathcal{P}) , if there exist some measures $d\bar{\eta}_i \in \mathcal{M}[0, T]$ and a costate $p \in BV([0, T], \mathbb{R}^{n*})$, such that:*

$$\dot{\bar{y}}(t) = f(\bar{u}(t), \bar{y}(t)) \text{ a.e. on } [0, T], \quad \bar{y}(0) = \bar{y}_0, \quad (2.3)$$

$$-d\bar{p}(t) = \bar{p}(t) f_y(\bar{u}(t), \bar{y}(t)) dt + \sum_{i=1}^r g'_i(\bar{y}(t)) d\bar{\eta}_i(t), \quad \bar{p}(T) = \phi'(\bar{y}(T)), \quad (2.4)$$

$$\bar{u}(t) \in \underset{\bar{u} \in \mathbb{R}^m}{\operatorname{argmin}} \{ \bar{p}(t) f(\bar{u}, \bar{y}(t)) \} \text{ a.e. on } [0, T], \quad (2.5)$$

$$0 \geq g_i(\bar{y}(t)), \quad d\bar{\eta}_i \geq 0, \quad \int_0^T g_i(\bar{y}(t)) d\bar{\eta}_i(t) = 0, \quad i = 1, \dots, r. \quad (2.6)$$

Observe that condition (2.5) is equivalent to the *Hamiltonian inequality*

$$H[\bar{p}(t)](\bar{u}(t), \bar{y}(t)) \leq H[\bar{p}(t)](u, \bar{y}(t)), \quad \text{for all } u \in \mathbb{R}^m, \text{ a.e. on } [0, T]. \quad (2.7)$$

The *linearized state equation* at (\bar{u}, \bar{y}) is

$$\dot{z}(t) = f'(\bar{u}(t), \bar{y}(t))(v(t), z(t)); \quad z(0) = 0, \quad (2.8)$$

whose solution is denoted by $z[v]$.

By **(A2)**, (\bar{u}, \bar{y}) satisfies the following constraints qualification [23] (cf. also [2]): there exists $\varepsilon_Q > 0$ and $v^\# \in L^\infty$ such that $z^\# = z[v^\#]$ satisfies

$$g_i(\bar{y}(t)) + g'_i[t]z^\#(t) < -\varepsilon_Q < 0, \quad t \in [0, T], \quad i = 1, \dots, r. \quad (2.9)$$

Any qualified solution of (\mathcal{P}) is a regular Pontryagin extremal, see e.g. [26]. But while the above qualification condition only guarantees the fact that the set of Lagrange multipliers is nonempty and bounded, **(A2)** implies the uniqueness of the Lagrange multiplier, see [6].

A trajectory (u, y) is a *stationary point* of (\mathcal{P}) , if there exist $\bar{\eta} \in \mathcal{M}[0, T]$ and $\bar{p} \in BV([0, T]; \mathbb{R}^{n^*})$ such that (2.3), (2.4), (2.6) hold, as well as

$$0 = H_u[\bar{p}(t)](\bar{u}(t), \bar{y}(t)) = \bar{p}(t)f_u(\bar{u}(t), \bar{y}(t)) \text{ for a.a. } t \in [0, T].$$

Obviously, a regular Pontryagin extremal is also a stationary point, and the converse holds if the Hamiltonian H is a convex function of the control for a.a. time. It is known [23] that qualified local solutions of (\mathcal{P}) are stationary points.

2.2. A key result. The next assumption is quite common in these problems and it plays a crucial role in the successive analysis. We assume that problem (\mathcal{P}) has a local solution (\bar{u}, \bar{y}) , with associated multipliers \bar{p} and $\bar{\eta}$ satisfying the following condition

(A3) (*Strengthened Legendre-Clebsch condition*) There exists $\alpha > 0$ such that

$$H_{uu}[\bar{p}(t)](\bar{u}(t), \bar{y}(t)) \geq \alpha, \text{ for a.a. } t \in [0, T]. \quad (2.10)$$

We recall that the continuity of the control was stated in **(A1)**. A sufficient condition for the continuity of the control, stronger than **(A3)**, is (see [5, Thm. 2]) the uniform strong convexity of the Hamiltonian w.r.t. the control variable, i.e. there exists $\alpha > 0$, such that

$$H_{uu}[\bar{p}(t)](\hat{u}(t), \bar{y}(t)) \geq \alpha, \text{ for a.a. } \hat{u} \in \mathbb{R}^m \text{ and for all } t \in [0, T]. \quad (2.11)$$

We recall also the following regularity result, due to [14] (see the generalization in [1]):

LEMMA 2.2. *Let **(A0)**-**(A3)** hold. Then both \bar{u} and $\bar{\eta}$ are Lipschitz continuous. In view of this Lemma, $\bar{\eta}$ has a density that we denote by $\nu(t)$, the costate is Lipschitz, and we may rewrite its dynamics as*

$$-\dot{\bar{p}}(t) = \bar{p}(t)f_y(\bar{u}(t), \bar{y}(t)) + \sum_{i=1}^r \nu_i(t)g'_i(\bar{y}(t)) \quad \text{a.e. on } (0, T); \quad \bar{p}(t) = \phi'(\bar{y}(T)). \quad (2.12)$$

In the rest of the paper we assume as standing hypothesis **(A0)**-**(A3)**.

2.3. Second Order Conditions and Alternative Formulation. Let us first recall some theoretical issues about second-order conditions. We introduce the linearized control and state space $\mathcal{V} := L^2(0, T)$ and $\mathcal{Z} := H^1(0, T; \mathbb{R}^n)$, resp. We use also the notations

$$H[t] := H[\bar{p}(t)](\bar{u}(t), \bar{y}(t)); \quad g[t] := g(\bar{y}(t)), \quad f[t] := f(u(t), y(t));$$

as well as for their partial derivatives, e.g. $H_u[t] := H_u[\bar{p}(t)](\bar{u}(t), \bar{y}(t))$, and other functions. The quadratic form over $\mathcal{V} \times \mathcal{Z}$ used in the second order conditions is, for $z = z[v]$:

$$\Omega(v) := \int_0^T \left(H_{yy}[t](v(t), z(t))^2 + \sum_{i=1}^r \nu_i(t) g_i''[t](z(t))^2 \right) dt + \phi''(\bar{y}(T))(z(T))^2, \quad (2.13)$$

and the set $C(\bar{u})$ of *critical directions* is defined as those $v \in \mathcal{V}$ such that, for $z = z[v]$:

$$\dot{z} = f_u(\bar{u}, \bar{y})v + f_y(\bar{u}, \bar{y})z \text{ on } [0, T]; \quad z(0) = 0, \quad (2.14)$$

$$g_i'(\bar{y}(t))z(t) = 0, \quad t \in I_i \quad (2.15)$$

$$\phi'(\bar{y}(T))z(T) = 0. \quad (2.16)$$

Note that in the last relation we write an equality instead of an inequality since this is known to be equivalent for qualified solutions, which will be the case thanks to assumption **(A2)**.

Let us next recall the *alternative formulation* of the optimality conditions, due to [8] and [17], and put on a sound mathematical basis by [19]. (See also [4]). The *alternative Hamiltonian* $H : \mathbb{R}^m \times \mathbb{R}^n \times \mathbb{R}^{n*} \times \mathbb{R}^{r*} \rightarrow \mathbb{R}$ is defined by:

$$\tilde{H}[p^1(t), \bar{\eta}^1](u, y) := p^1 f(u, y) + \bar{\eta}^1 g^{(1)}(u, y). \quad (2.17)$$

Now define the alternative costate and multiplier of the state constraint:

$$p^1(t) := \bar{p}(t) + \sum_{i=1}^r \bar{\eta}(t) g_i'(\bar{y}(t)); \quad \bar{\eta}^1(t) := -\bar{\eta}(t), \quad t \in (0, T).$$

It is easily checked that

$$-\dot{p}^1(t) = \tilde{H}_y[p^1(t), \bar{\eta}^1(t)](\bar{u}(t), \bar{y}(t)) \quad \text{a.e. on } (0, T); \quad p^1(T) = \phi'(\bar{y}(T)). \quad (2.18)$$

At the same time, for any $u \in \mathbb{R}$, we have that

$$\tilde{H}[p^1(t), \bar{\eta}^1(t)](u, \bar{y}(t)) = (p^1(t) + \bar{\eta}^1(t) g'(\bar{y}(t))) f(u, \bar{y}(t)) = H[\bar{p}(t)](u, \bar{y}(t)).$$

Consequently the property of stationarity or minimization of the Hamiltonian w.r.t. the control holds for the original Hamiltonian H if and only if it holds for the alternative Hamiltonian \tilde{H} .

The corresponding alternative quadratic form, where $z = z[v]$, has the following expression:

$$\tilde{\Omega}(v) := \int_0^T \tilde{H}_{yy}[t](v(t), z(t))^2 dt + \phi''(\bar{y}(T))(z(T))^2.$$

The form above involves the expression of $D^2 g^{(1)}[t]$, which is easily checked to be

$$D^2 g^{(1)}[t](v, z)^2 = g^{(3)}[t](f[t], z, z) + g'[t] f_{yy}[t](v, z)^2 + 2g''[t](z, f_y[t](v, z)). \quad (2.19)$$

The next Lemma is a variant of some results by Bonnans and Hermant [4], Malanowski and Maurer [18]. We give a short, direct proof in the case of a single constraint for convenience.

LEMMA 2.3. *We have that $\tilde{\Omega}(v) = \Omega(v)$, for all $v \in \mathcal{U}$.*

Proof. Using (2.19), we get that

$$\begin{aligned} \int_0^T \nu(t)g''[t](z(t))^2 dt &= \int_0^T g''[t](z(t))^2 d\bar{\eta}(t) = \int_0^T \frac{d}{dt} (g''[t](z(t))^2) \bar{\eta}^1(t) dt \\ &= \int_0^T \left(g^{(3)}(\bar{y}(t))(f[t], z(t), z(t)) + 2g''[t](z(t), \dot{z}(t)) \right) \bar{\eta}^1(t) dt \\ &= \int_0^T \left(D^2 g^{(1)}[t](v(t), z(t))^2 - g'[t]f_{yy}[t](v(t), z(t))^2 \right) \bar{\eta}^1(t) dt. \end{aligned}$$

Eliminating $\bar{p}(t) = p^1(t) + \bar{\eta}^1 g'[t]$ in the expression of $\Omega(\cdot)$, we obtain that

$$\begin{aligned} \Omega(v) &= \int_0^T \left((p^1(t) + \bar{\eta}^1(t)g'[t])f_{yy}[t](v(t), z(t))^2 + \nu(t)g''[t](z(t))^2 \right) dt \\ &\quad + \phi''(\bar{y}(T))(z(T))^2 \\ &= \int_0^T \left(p^1(t)f_{yy}[t](v(t), z(t))^2 + \bar{\eta}^1(t)D^2 g^{(1)}[t](v(t), z(t))^2 \right) dt \\ &\quad + \phi''(\bar{y}(T))(z(T))^2, \end{aligned}$$

as which was to be proved. \square

2.4. Discrete version. We introduce now the Euler discretization of the optimal control problem (2.1). Given some non zero $N \in \mathbb{N}$ and a collection of positive time steps h_k , $k = 0$ to $N - 1$, such that $\sum_{k=0}^{N-1} h_k = T$, we set

$$t_k := \sum_{i=0}^{k-1} h_i, \quad k = 0, \dots, N; \quad \bar{h} = \max_{k=0, \dots, N-1} h_k,$$

and we consider the discretized problem

$$(\mathcal{P}_d) \begin{cases} \text{Minimize } \phi(y_N); & \text{subject to} \\ y_{k+1} = y_k + h_k f(u_k, y_k), & \text{for } k = 0, \dots, N-1; \\ y_0 = y_0; \\ g(y_k) \leq 0 & \text{for } k = 1, \dots, N. \end{cases} \quad (2.20)$$

The associated Lagrangian function (with a proper scaling of the state constraint) is

$$\phi(y_N) + \sum_{k=0}^{N-1} p_{k+1}(y_k + h_k f(u_k, y_k) - y_{k+1}) + \sum_{k=1}^N h_k \nu_k g(y_k),$$

where $\nu_k g(y_k) = \sum_{i=1}^r \nu_{k,i} g_i(y_k)$. The first-order optimality conditions (in qualified form), for this finite dimensional optimization problem with finitely many equalities and inequalities, are

$$\begin{aligned} p_k &= p_{k+1} + h_k p_{k+1} f_y(u_k, y_k) + h_k \nu_k g'(y_k), \quad k = 0, \dots, N-1, \\ p_N &= \phi'(y_N) + h_N \nu_N g'(y_N), \\ 0 &= H_u[p_{k+1}](u_k, y_k), \quad k = 0, \dots, N-1, \\ g_i(y_k) &\leq 0, \quad \nu_{k,i} \geq 0; \quad \nu_{k,i} g_i(y_k) = 0, \quad i = 1, \dots, r, \quad k = 0, \dots, N. \end{aligned} \quad (2.21)$$

Analogously to the continuous case we define also the ‘‘integrated’’ multiplier of the normal and the alternative formulation

$$\eta_k := - \sum_{j=k}^N h_j \nu_j, \quad \bar{\eta} := -\eta, \quad (2.22)$$

so that $h_k \nu_k = \eta_{k+1} - \eta_k = \bar{\eta}_k - \bar{\eta}_{k+1}$, for $k = 0, \dots, N$.

DEFINITION 2.4. *We say that the discretization step is constant if*

$$h_0 = h_1 = \dots = h_{N-1}. \quad (2.23)$$

2.5. Main result. As mentioned before, our results hold in two different cases. We need to preserve the coercivity of the Hessian of the Lagrangian over some subspace; this can be stated as hypothesis, as in [13] or obtained under structure hypotheses for a scalar state constraints. So we will assume that one of the following assumptions hold:

(A4) There exists a constant $\alpha > 0$ such that

$$\Omega(v) \geq \alpha \int_0^T v(t)^2 dt, \quad \text{for all } v \in \mathcal{V}$$

and all discrete steps are of the same order, i.e.

$$\max_k (h_k/h_{k-1} + h_{k-1}/h_k) = O(1). \quad (2.24)$$

(A5) (*scalar constraint and finite structure*) Assume that $r = 1$, the discretization step is constant, the set I is a finite union of boundary arcs, the density ν is uniformly positive over the boundary arcs, and there exists a constant $\alpha > 0$ such that

$$\Omega(v) \geq \alpha \int_0^T v(t)^2 dt, \quad \text{whenever } v \in C(\bar{u}). \quad (2.25)$$

Note that (A5) excludes *touch points*, i.e., isolated elements of I_i , for $i = 1, \dots, r$. We denote by \mathcal{I}^b the union of boundary arcs, of the form $\mathcal{I}^b := \cup_{j=1}^{N_b} [\mathcal{T}_j^{en}, \mathcal{T}_j^{ex}]$ where we have ordered the set of entry points $\mathcal{T}^{en} := \{\mathcal{T}_1^{en} < \dots < \mathcal{T}_{N_b}^{en}\}$, and similarly for the set \mathcal{T}^{ex} of exit points.

In the rest of the paper the results presented are valid for the choice of a fixed $\varepsilon > 0$ sufficiently small and a successive choice of a $\bar{h} := \max_k h_k$, enough small in relation with ε .

THEOREM 2.5. *Let assumptions (A0)-(A3) hold as well as either (A4) or (A5). Then the discrete optimal control problem (\mathcal{P}_d) has a local solution (u^h, y^h) with associated multipliers (p^h, η^h) , such that*

$$\|y^h - \bar{y}\|_\infty + \|u^h - \bar{u}\|_\infty + \|p^h - \bar{p}\|_\infty + \|\eta^h - \bar{\eta}\|_\infty = O(\bar{h}). \quad (2.26)$$

The rest of the paper will be dedicated to the proof of this result; for that purpose we need to introduce a special auxiliary problem.

3. Homotopy path. We consider a family (\mathcal{P}^θ) of perturbed discrete optimization problems, parametrized by $\theta \in [0, 1]$. The definition is done such that for $\theta = 0$, the problem reduces to (\mathcal{P}_d) . As we will see in the next Section, a certain sampling of the solution of the continuous problem (\mathcal{P}) happens to be a solution of (\mathcal{P}^1) . The

perturbed optimal control problem is, for some perturbations terms $\delta^p, \delta^u, \delta^y, \delta^g$, defined such that $\|\delta\|_\infty = O(1)$,

$$(\mathcal{P}^\theta) \begin{cases} \text{Minimize } \phi(y_N^\theta) + \theta \sum_{k=0}^{N-1} h_k^2 (\delta_k^p y_k^\theta + \delta_k^u u_k^\theta); & \text{subject to} \\ y_{k+1}^\theta = y_k^\theta + h_k f(u_k^\theta, y_k^\theta) + \theta h_k^2 \delta_k^y, & \text{for } k = 0, \dots, N-1; \\ g_i(y_k^\theta) \leq \theta h_k^2 \delta_k^g, & \text{for } k = 1, \dots, N, \\ y_0^\theta = y_0, & i = 1, \dots, r. \end{cases} \quad (3.1)$$

The corresponding optimality system is

$$\begin{aligned} p_k^\theta &= p_{k+1}^\theta + h_k p_{k+1}^\theta f_y(u_k^\theta, y_k^\theta) + h_k \nu_k^\theta g'(y_k^\theta) + \theta h_k^2 \delta_k^p, \\ p_N^\theta &= \phi'(y_N^\theta) + h_N \nu_N^\theta g'(y_N^\theta), \\ 0 &= H_u[p_{k+1}^\theta](u_k^\theta, y_k^\theta) + \theta h_k \delta_k^u, \end{aligned} \quad (3.2)$$

for $k = 1$ to $N-1$, with the complementarity conditions, $i = 1, \dots, r$,

$$g_i(y_k^\theta) - \theta h_k^2 \delta_k^g \leq 0, \quad \nu_{k,i}^\theta \geq 0, \quad \nu_{k,i}^\theta (g_i(y_k^\theta) - \theta h_k^2 \delta_k^g) = 0, \quad k = 1, \dots, N. \quad (3.3)$$

Let us set

$$f^k := (u_k^\theta, y_k^\theta); \quad H^k := H[p_{k+1}^\theta](u_k^\theta, y_k^\theta) \quad (3.4)$$

For future reference we note that the linearization of the costate equation is, denoting by $(v^\theta, z^\theta, q^\theta, \delta \nu^\theta)$ the linearizations of $(u^\theta, y^\theta, p^\theta, \nu^\theta)$ when the state constraint is not active at the final time:

$$\begin{aligned} q_k^\theta &= q_{k+1}^\theta + h_k q_{k+1}^\theta f_y^k + h_k (v_k^\theta)^T H_{uy}^k + h_k (z_k^\theta)^T H_{yy}^k \\ &\quad + h_k \nu_k^\theta (z_k^\theta)^T g''(y_k^\theta) + h_k \delta \nu_k^\theta g'(y_k^\theta) - \theta h_k^2 \delta_k^p, \\ q_N^\theta &= (z_N^\theta)^T \phi''(y_N^\theta) + h_N \nu_N^\theta (z_N^\theta)^T g''(y_N^\theta) + h_N \delta \nu_N^\theta g'(y_N^\theta). \end{aligned} \quad (3.5)$$

The corresponding approximation of $\bar{\eta}$ is: (see (2.22))

$$\eta_k^\theta := - \sum_{j=k}^N h_j \nu_j^\theta, \quad k = 0, \dots, N. \quad (3.6)$$

The *sampling* of the continuous solution and the associated multipliers of the original problem (2.1) are defined by

$$\begin{cases} \hat{u}_k &:= \bar{u}(t_k), \quad \hat{y}_k := \bar{y}(t_k), & k = 0, \dots, N-1, \\ \hat{p}_k &:= \bar{p}(t_k), \quad \hat{\nu}_k := \int_{t_k}^{t_{k+1}} \nu(t) dt, & k = 1, \dots, N, \end{cases} \quad (3.7)$$

and accordingly we can define

$$\hat{\eta}_k := \eta(t_{k+1}) = \sum_{j=k}^N h_k \hat{\nu}_k, \quad k = 1, \dots, N.$$

We next define the perturbation terms $(\delta_k^u, \delta_k^y, \delta_k^p, \delta_k^g)$ in such a way that the above sampling is solution of the discretized problem for $\theta = 1$.

LEMMA 3.1. *If we define $\delta^u, \delta^y, \delta^p, \delta^g$ such that for $\theta = 1$:*

$$u_k^\theta = \hat{u}_k, \quad y_k^\theta = \hat{y}_k, \quad p_k^\theta = \hat{p}_k, \quad \eta_k^\theta = \hat{\eta}_k, \quad \text{for } k = 1, \dots, N. \quad (3.8)$$

Then we have that

$$\|\delta^y\|_\infty + \|\delta^u\|_\infty + \|\delta^p\|_\infty + \|\delta^g\|_\infty = O(1). \quad (3.9)$$

Proof. Since u is Lipschitz continuous by lemma 2.2, $t \rightarrow g(y_t)$ has a.e. a bounded second derivative. Therefore, if $\nu_k \neq 0$ there exists some $c > 0$ such that $g(y_t) \geq -c\bar{h}^2$ for all $t \in [t_k, t_{k+1}]$, so that $\|\delta^g\|_\infty = O(1)$.

Next, if $w : [0, T] \rightarrow \mathbb{R}$ is C^1 with a Lipschitz continuous derivative of constant L , then by a first order Taylor expansion, we have that

$$|w(t+h) - w(t) - w'(t)h| \leq \frac{1}{2}Lh^2.$$

By Lemma 2.2, the control is Lipschitz. As well as $\dot{y}(t)$; we deduce that $\|\delta^y\|_\infty = O(1)$. For the costate equation, we have that

$$\bar{p}(t_{k+1}) = \bar{p}(t_k) - \int_{t_k}^{t_{k+1}} \bar{p}(t)f_y[t]dt - \int_{t_k}^{t_{k+1}} \nu(t)g'[t]dt.$$

Now since \bar{u} , \bar{y} , and \bar{p} are Lipschitz,

$$\left| \int_{t_k}^{t_{k+1}} \bar{p}(t)f_y(\bar{u}(t), \bar{y}(t))dt - \int_{t_k}^{t_{k+1}} \bar{p}(t_{k+1})f_y(\bar{u}(t_k), \bar{y}(t_k))dt \right| = O(h_k^2),$$

and (in the parenthesis below we recognize the expression of ν_k):

$$\left| \int_{t_k}^{t_{k+1}} \nu(t)g'[t]dt - \left(\int_{t_k}^{t_{k+1}} \nu(t)dt \right) g'(\bar{y}(t_k)) \right| = O(h_k^2).$$

It follows that $\|\delta^p\|_\infty = O(1)$. Since p is Lipschitz and $H_u[p(t_k)](\bar{u}(t_k), \bar{y}(t_k)) = 0$ we easily deduce that $\|\delta^u\|_\infty = O(1)$. The conclusion follows. \square

Given $\varepsilon > 0$ and $\theta \in [0, 1]$, we say that a solution $X^\theta := (u^\theta, y^\theta, p^\theta, \eta^\theta)$ of the optimality system (3.2) is an ε -neighbouring solution if we have that

$$\|u^\theta - \hat{u}\|_\infty + \|y^\theta - \hat{y}\|_\infty + \|p^\theta - \hat{p}\|_\infty + \|\eta^\theta - \hat{\eta}\|_\infty \leq \varepsilon, \quad (3.10)$$

and we define

$$\theta_m := \inf\{\theta \in [0, 1]; (3.2) \text{ has an } \varepsilon\text{-neighbouring solution}\}.$$

When $\theta = 1$, the l.h.s. of (3.10) has value 0, and therefore θ_m is well-defined with value in $[0, 1]$.

Through the auxiliary structure of the homotopy path problem we are now able to prove the bounds shown in Theorem 2.5. Afterwards some technical points will be reprised and clarified. In particular we will use the fact that the solution of (\mathcal{P}^θ) is uniformly Lipschitz continuous (the result is contained in Section 4) and that such solution is in a ε -neighbourhood of the solution of (\mathcal{P}) , $X^1 = (\bar{u}, \bar{y}, \bar{p}, \bar{\eta})$; this point will be discussed in Section 5.

Proof. [of Th. 2.5.] We prove in Section 4 that, if \bar{h} is small enough, for $\theta \in [\theta_m, 1]$, then (u^θ, y^θ) is uniquely defined, has unique associated multipliers (p^θ, η^θ) , and setting $X^\theta := (u^\theta, y^\theta, p^\theta, \eta^\theta)$, (see Section 5) $\theta \rightarrow X^\theta$ has Lipschitz constant of order \bar{h} . It follows that $\|X^\theta - X^1\|_\infty < \varepsilon$ when \bar{h} is small enough, which gives a contradiction if $\theta_m > 0$. Therefore, X^0 is well-defined and $\|X^1 - X^0\|_\infty = O(\bar{h})$, which had to be shown. \square

4. Regularity of the solutions. In this Section we present some regularity results for the solutions of the Homotopy path problem.

Given an ε -neighbouring solution X^θ of (\mathcal{P}^θ) , we will prove the uniqueness and the uniform Lipschitz continuity of X^θ . In the following, when there is no possibility of confusion, we drop θ as upper index in the notation for a better readability. We need to define

$$\begin{aligned} C_k^1 &:= \frac{p_k}{h_k} (f_u(u_{k-1}, y_k) - f_u(u_{k-1}, y_{k-1})), \\ C_k^2 &:= p_{k+1} f_y(u_k, y_k) f_u(u_k, y_k), \\ \Delta_k^u &:= h_k \delta_k^u - h_{k-1} \delta_{k-1}^u \\ &= (\hat{p}_k - \hat{p}_{k+1}) f_u(\hat{u}_k, \hat{y}_k) - (\hat{p}_{k-1} - \hat{p}_k) f_u(\hat{u}_{k-1}, \hat{y}_{k-1}). \\ C_k^3 &:= C_k^1 - C_k^2 - \theta h_k \delta_k^p f_u(u_k, y_k) + \theta \Delta_k^u / h_k. \end{aligned} \quad (4.1)$$

Observe that, since y_k^θ is uniformly Lipschitz we have that:

$$(i) \quad C_k^1 = \frac{h_{k-1}}{h_k} H_{uy}[p_k](u_{k-1}, y_k) f(u_{k-1}, y_{k-1}) + O(\bar{h}); \quad (ii) \quad |C_k^3| = O(1). \quad (4.2)$$

LEMMA 4.1. (i) Let X^θ be an ε -neighbouring solution of (\mathcal{P}^θ) . If $\varepsilon > 0$ and \bar{h} are small enough, then

$$\sum_{j=1}^r \nu_{k,j}^\theta \nabla_u g_j^{(1)}(u_k^\theta, y_k^\theta) = \mathcal{H}_k^\theta \frac{(u_k^\theta - u_{k-1}^\theta)}{h_k} + C_k^3, \quad (4.3)$$

where \mathcal{H}_k^θ is such that

$$|\mathcal{H}_k^\theta - H_{uu}[p_k](u_k, y_k)| = O(\varepsilon). \quad (4.4)$$

(ii) Let $\varepsilon' > 0$. If in addition, the time step is constant, t_k belongs to a boundary arc (t_a, t_b) , and $t_{k_a} + \varepsilon' < t_{k-1} < t_k < t_{k_b} - \varepsilon'$, then the variation of C_k^3 along the homotopy path is of order $O(\bar{h})$.

Proof. (i) Note that $h_k \delta_k^u = (\hat{p}_k - \hat{p}_{k+1}) f_u(\hat{u}_k, \hat{y}_k)$. By the optimality condition (3.2), we have that

$$\begin{aligned} 0 &= H_u[p_{k+1}](u_k, y_k) - H_u[p_k](u_{k-1}, y_{k-1}) + \theta \Delta_k^u \\ &= p_{k+1} f_u(u_k, y_k) - p_k f_u(u_{k-1}, y_{k-1}) + \theta \Delta_k^u \\ &= (p_{k+1} - p_k) f_u(u_k, y_k) + p_k [f_u(u_k, y_k) - f_u(u_{k-1}, y_{k-1})] + \theta \Delta_k^u \\ &= (p_{k+1} - p_k) f_u(u_k, y_k) + p_k [f_u(u_k, y_k) - f_u(u_{k-1}, y_k)] + h_k C_k^1 + \theta \Delta_k^u. \end{aligned} \quad (4.5)$$

By the mean-value Theorem, we deduce that

$$p_k (f_u(u_k, y_k) - f_u(u_{k-1}, y_k)) = \mathcal{H}_k (u_k - u_{k-1}),$$

where

$$\mathcal{H}_k := p_k \int_0^1 f_u(u_{k-1} + \sigma(u_{k-1} - u_k), y_k) (u_{k-1} - u_k) d\sigma,$$

so that (4.4) holds. We conclude by combining (4.5) and the discrete costate equation in (3.2), where $\nabla_u g_i^{(1)}(u_k, y_k) = g_i'(y_k) f_u(u_k, y_k)$.

(ii) It is easily checked that C_k^1 and C_k^2 satisfy this property, as well as (it is of order of \bar{h}) $\theta h_k \delta_k^p f_u(u_k, y_k)$. Since the time step is constant, we have that by (4.1) $\Delta_k^u/h_k = \delta_k^u - \delta_{k-1}^u$ is of order of \bar{h} over the interior of a boundary arc. The conclusion follows. \square

Set

$$\Delta_g^{k,i} := \frac{g_i(y_{k+1}) - g_i(y_k)}{h_k} - \frac{g_i(y_k) - g_i(y_{k-1})}{h_{k-1}}. \quad (4.6)$$

LEMMA 4.2. *We have that:*

a) *the following relation holds*

$$\begin{aligned} \Delta_g^{k,i} &= g'_i(y_k) f_u(u_k, y_k)(u_k - u_{k-1}) + g'_i(y_k) (f(u_{k-1}, y_k) - f(u_{k-1}, y_{k-1})) \\ &\quad + \theta g'_i(y_k) (h_k \delta_k^y - h_{k-1} \delta_{k-1}^y) + \frac{1}{2} h_k g''_i(y_k) f(u_k, y_k)^2 \\ &\quad + \frac{1}{2} h_{k-1} g''_i(y_k) f(u_{k-1}, y_{k-1})^2 + O(\varepsilon |u_k - u_{k-1}|) + O(\bar{h}^2), \end{aligned} \quad (4.7)$$

b) *If in addition the time step is constant, then*

$$\begin{aligned} \Delta_g^{k,i} &= g'_i(y_k) f_u(y_k, u_k)(u_k - u_{k-1}) + \bar{h} \Xi_k^\theta \\ &\quad + O(\bar{h}^2) + O(\varepsilon |u_k - u_{k-1}|), \end{aligned} \quad (4.8)$$

where Ξ_k^θ is such that $\|\Xi^\theta - \Xi^1\|_\infty = O(\varepsilon)$.

Proof. Use

$$\begin{aligned} g_i(y_{k+1}) - g_i(y_k) &= g'_i(y_k)(y_{k+1} - y_k) + \frac{1}{2} g''_i(y_k)(y_{k+1} - y_k)^2 + O(h_k^3), \\ &= h_k g'_i(y_k) f(u_k, y_k) \\ &\quad + \frac{1}{2} h_k^2 (2\theta g'(y_k) \delta_k^y + g''_i(y_k) f(u_k, y_k)^2) + O(h_k^3), \\ g_i(y_{k-1}) - g_i(y_k) &= g'_i(y_k)(y_{k-1} - y_k) + \frac{1}{2} g''_i(y_k)(y_{k-1} - y_k)^2 + O(h_k^3), \\ &= -h_{k-1} g'_i(y_k) f(u_{k-1}, y_{k-1}) \\ &\quad + \frac{1}{2} h_{k-1}^2 (-2\theta g'_i(y_k) \delta_{k-1}^y + g''_i(y_k) f(u_{k-1}, y_{k-1})^2) \\ &\quad + O(h_{k-1}^3). \end{aligned}$$

We obtain a) by dividing these relations by h_k and h_{k-1} respectively, adding them and observing

$$\begin{aligned} f(u_k, y_k) - f(u_{k-1}, y_{k-1}) &= f(u_k, y_k) - f(u_{k-1}, y_k) + f(u_{k-1}, y_k) - f(u_{k-1}, y_{k-1}) \\ &= f_u(u_k, y_k)(u_k - u_{k-1}) + (f(u_{k-1}, y_k) - f(u_{k-1}, y_{k-1})) + O(\varepsilon |u_k - u_{k-1}|). \end{aligned}$$

Since $|y_k - y_{k-1}| = O(h_{k-1})$, point (b) follows using that $h_k = h_{k-1}$ and $|\delta_k^y - \delta_{k-1}^y| = O(\bar{h})$. \square

Now we are ready to show the regularity of the variables of the perturbed problem. A similar result, in the continuous case has been formulated in [12]. Let us set

$$w_k = \nu_k \nabla_u g^{(1)}(u_k, y_k) = \sum_{i=1}^r \nu_{k,i} \nabla_u g_i^{(1)}(u_k, y_k). \quad (4.9)$$

LEMMA 4.3. *We have that*

$$w_k^T \mathcal{H}_k^{-1} w_k = \frac{1}{h_k} w_k \cdot (u_k - u_{k-1}) + w^T \mathcal{H}_k^{-1} C_k^3, \quad (4.10)$$

as well as

$$\text{Lip}(u^\theta) + \text{Lip}(p^\theta) + \|\nu^\theta\|_\infty = O(1).$$

Proof. By the Legendre-Clebsch condition **(A3)**, for small enough $\varepsilon > 0$, \mathcal{H}_k is uniformly invertible. Computing the scalar product of both sides of (4.3) by $w_k^T \mathcal{H}_k^{-1}$, we obtain (4.10).

When $\nu_{k,i} \neq 0$ we have that $g_{k,i}^\theta := g_i(y_k) - \theta h_k^2 \delta_{k,i}^g$ reaches a local maximum and therefore

$$0 \geq \frac{g_{k+1,i}^\theta - g_{k,i}^\theta}{h_k} - \frac{g_{k,i}^\theta - g_{k-1,i}^\theta}{h_{k-1}},$$

which amounts to

$$\Delta_g^{k,i} \leq \theta \left(\frac{h_{k+1}^2 \delta_{k+1,i}^g - h_k^2 \delta_{k,i}^g}{h_k} - \frac{h_k^2 \delta_{k,i}^g - h_{k-1}^2 \delta_{k-1,i}^g}{h_{k-1}} \right) \leq O(\bar{h}). \quad (4.11)$$

Since $|C_k^3| = O(1)$ as already noticed, it follows from (4.3) that $|u_k - u_{k-1}|/h_k = O(|\nu_k| + 1)$. Now putting it together with (4.7) and (4.11), it follows that

$$\frac{1}{h_k} w_k \cdot (u_k - u_{k-1}) + w^T \mathcal{H}^{-1} C_k^3 \leq \frac{1}{h_k} \sum_{i=1}^r \nu_k \Delta_g^{k,i} + O(1) + O(\|\nu_k\|), \quad (4.12)$$

then for the linear independence of the constraints w.r.t. the control (Assumption **(A2)**), i.e. $|w_k| \geq \alpha \|\nu_k\|$, in the l.h.s. of (4.10), we have

$$\alpha \|\nu_k\|^2 \leq O(\|\nu_k\|) + O(1). \quad (4.13)$$

By the above display, $\|\nu_k\| = O(1)$, and by (4.3), u_k is uniformly Lipschitz. By (3.2), also p_k is uniformly Lipschitz continuous. \square

5. Sensitivity analysis.

5.1. Characterization of directional derivatives. In this Section we complete the proof of Theorem 2.5 showing that a solution (u^θ, y^θ) of the perturbed problem (\mathcal{P}^θ) is in a L^∞ neighbourhood of (\bar{u}, \bar{y}) , local solution of the problem (\mathcal{P}) . The strategy consists in establishing that the path $X^\theta := (u^\theta, y^\theta, p^\theta, \eta^\theta)$ is Lipschitz, and then to show that it has directional derivatives $\delta X^\theta := (v^\theta, z^\theta, q^\theta, \delta \eta^\theta)$ satisfying $\|\delta X^\theta\|_\infty = O(\bar{h})$. This will imply that the Lipschitz constant of X^θ (in the L^∞ norm) is of order $O(\bar{h})$.

The fact that X^θ is Lipschitz is a consequence of Robinson's theory for strong regularity [24] and its application to nonlinear programming see e.g. [3, Sec. 5.1]. This theory gives a sufficient condition for Lipschitz stability of the local solution and associated multiplier, provided that we have the (i) linear independence of gradients of active constraints, which by **(A2)** always holds, and (ii) positivity of the Hessian of the Lagrangian over an *extended critical cone*, obtained by removing inequality constraints associated with zero components of the multiplier, as well as the condition on the linearization of the cost function. In addition, under these conditions, Jittorntrum's

result [22] states that directional derivatives exist and that they are solution of the following quadratic programming problem

$$(QP) \begin{cases} \text{Min}_v \frac{1}{2} \Omega^\theta(v) - \theta \sum_{k=0}^{N-1} h_k^2 (\delta_k^p z_k + \delta_k^u v_k) & \text{s.t. } z = z^\theta[v] \text{ and} \\ g'_i(y_k) z_k = -\theta h_k^2 \delta_k^g & k \in I_+^{i,\theta}, \text{ s.t. } \nu_k \neq 0, \\ g'_i(y_k) z_k \leq -\theta h_k^2 \delta_k^g & k \in I_0^{i,\theta}, \text{ s.t. } \nu_k = 0, \end{cases} \quad (5.1)$$

Here $v \in \mathcal{V}^N$, $z^\theta[v] \in \mathcal{Z}^N$ is defined as the unique solution of the linearized state equation

$$z_{k+1}^\theta = z_k^\theta + h_k f_y(u_k, y_k)(v_k, z_k^\theta) - \theta h_k^2 \delta_k^y, \quad k = 0, \dots, N-1, \quad i = 1, \dots, r, \quad (5.2)$$

and the set of constraints $I_+^{i,\theta}$ and $I_0^{i,\theta}$ are defined as the inequality constraints of problem (\mathcal{P}^θ) that are active at y^θ , i.e.:

$$\begin{cases} I_+^{i,\theta} & := \{k = 0, \dots, N; \nu_i^\theta > 0\}, \\ I_0^{i,\theta} & := \{k = 0, \dots, N; \nu_i^\theta = g_i(y_k^\theta) = 0\}. \end{cases} \quad (5.3)$$

Finally, the Hessian of Lagrangian of the discretized problem is, with obvious notations, setting $H_k^\theta := p_{k+1}^\theta f(u_k^\theta, y_k^\theta)$, and for $z^\theta = z^\theta[v]$:

$$\Omega^\theta(v, z) := \sum_{k=0}^{N-1} h_k D^2 H_k^\theta(v_k, z_k^\theta)^2 + \sum_{k=0}^N h_k \nu_k D^2 g_k^\theta(z_k^\theta)^2 + \phi''(y_N^\theta)(z_N^\theta)^2. \quad (5.4)$$

Given $v \in \mathcal{V}^N$, we denote by \bar{v} the associated corresponding piecewise constant element defined by

$$\bar{v}(t) = v_k, \quad t \in (t_k, t_{k+1}), \quad \text{for all } k = 0 \text{ to } N-1.$$

Note that v and \bar{v} have the same L^s , $s \in [1, \infty]$ norm. Setting $\bar{z} := z[\bar{v}]$ (solution of the linearized state equation (2.8) for the original (continuous time) problem, we easily check that

$$\|z^\theta - \bar{z}\|_\infty = \|v\|_\infty O(\varepsilon + \bar{h}). \quad (5.5)$$

We anticipate a result that will be shown in details later (Corollary 5.6) about the existence and uniqueness of the solution of (QP) :

PROPOSITION 5.1. *Let **(A0)**–**(A3)** and, either **(A4)** or **(A5)** hold. Then problem (QP) has a unique solution $\delta X^\theta := (v^\theta, z^\theta, q^\theta, \delta \eta^\theta)$.*

Let us introduce the following *alternative formulation*: we underline the analogy with the alternative formulation recalled in Section 2.3. We first define the set of inequality constraints that are active at the solution of (QP) :

$$I^{i,\theta} := I_+^{i,\theta} \cup \{k \in I_0^{i,\theta}; g'_i(y_k^\theta) z_k^\theta = 0\}. \quad (5.6)$$

For $i = 1, \dots, r$, set $k_{i,0} := 0$, denote by $k_{i,1} < \dots < k_{i,M_i^\theta}$ the elements of $I^{i,\theta}$, and set and for $j = 0, \dots, M_i^\theta - 1$:

$$\begin{cases} \Delta t_{i,j} & := t_{k_{i,j+1}} - t_{k_{i,j}}, \\ b_{i,j}^E & := -\theta (h_{k_{i,j+1}}^2 \delta_{k_{i,j+1}}^g - h_{k_{i,j}}^2 \delta_k^g) / \Delta t_{i,j}. \end{cases} \quad (5.7)$$

Set

$$G_k(v_k, z_k) := \frac{g'(y_{k+1}) - g'(y_k)}{h_k} z_k + g'(y_{k+1}) f'(u_k, y_k)(v_k, z_k) - \theta h_k \delta_k^y. \quad (5.8)$$

If $z = z^\theta[v]$, then

$$G_k(v_k, z_k) = \frac{g'(y_{k+1})z_{k+1} - g'(y_k)z_k}{h_k}. \quad (5.9)$$

Since $z_0 = 0$, it follows that:

$$g'(y_k^\theta)z_k = \sum_{j < k} h_k G_k(v_k, z_k). \quad (5.10)$$

So the solution of (QP) satisfies the following equality constraints, called $G_{i,k}$ the i -component of G_k :

$$\sum_{j < k} h_k G_{i,k}(v_k, z_k) = -\theta h_k^2 \delta_{i,k}^g, \quad i = 1, \dots, r, \quad j = 0, \dots, M_i^\theta - 1. \quad (5.11)$$

An equivalent set of equality constraints is

$$b_{i,j}^E - \frac{1}{\Delta t_{i,j}} \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k G_{i,k}(v_k) = 0, \quad i = 1, \dots, r, \quad j = 0, \dots, M_i^\theta - 1. \quad (5.12)$$

The corresponding quadratic problem is

$$(QP_E) \begin{cases} \text{Min}_v \frac{1}{2} \Omega^\theta(v) - \theta \sum_{k=0}^{N-1} h_k^2 (\delta_k^p z_k + \delta_k^u v_k) \\ \text{s.t. } z = z^\theta[v] \text{ and (5.12).} \end{cases} \quad (5.13)$$

We call $\delta \bar{\eta}^\theta$ the multiplier associated with constraints (5.12) and \hat{q} the costate. The Lagrangian of (QP_E) is by the definition

$$\begin{aligned} \Omega^\theta(v, z) &+ \sum_{k=0}^{N-1} \hat{q}_{k+1} (h_k f'_k(v_k, z_k) + z_k - z_{k+1}) \\ &+ \sum_{i,j} \Delta t_{i,j} \delta \bar{\eta}_{i,j} \left(b_{i,j}^E - \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k G_k(v_k, z_k) / \Delta t_{i,j} \right). \end{aligned} \quad (5.14)$$

Given $k \leq M_i^\theta$, set

$$j(i, k) := \min\{j \in I^{i,\theta}; j \geq k + 1\}. \quad (5.15)$$

and also set

$$h_k \delta \bar{\nu}_k = \delta \bar{\eta}_{i,j(i,k-1)} - \delta \bar{\eta}_{i,j}. \quad (5.16)$$

The optimality conditions of (QP_E) have the following form. The costate equation is

$$\begin{aligned} \hat{q}_k^\theta &= \hat{q}_{k+1}^\theta + h_k \hat{q}_{k+1}^\theta f_y^k + h_k (v_k^\theta)^T H_{u_y}^k + h_k (z_k^\theta)^T H_{y_y}^k + h_k \nu_k (z_k^\theta)^T g''(y_k) \\ &\quad - \sum_{i=1}^r \delta \bar{\eta}_{i,j(i,k)}^\theta (g'(y_{k+1}) - g'(y_k) + h_k g'(y_{k+1}) f_y(u_k, y_k)) - \theta h_k^2 \delta_k^p; \\ \hat{q}_N^\theta &= (z_N^\theta)^T \phi''(y_N^\theta) + h_N \nu_N (z_N^\theta)^T g''(y_N). \end{aligned} \quad (5.17)$$

Expressing the stationarity of the Lagrangian w.r.t. v we get that

$$\begin{aligned} \text{(i)} \quad & (v_k)^T H_{uu}^k + (z_k)^T H_{uy}^k + \left(\hat{q}_{k+1}^\theta - \sum_{i=1}^r \delta \bar{\eta}_{i,j}^\theta g_y(u_k, y_k) \right) f_u^k = 0, \\ \text{(ii)} \quad & \frac{1}{\Delta t_{i,j}} \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k G_{i,k}(v_k) = \bar{b}_{i,j}. \end{aligned} \quad (5.18)$$

The first row suggests to define

$$\begin{aligned} \tilde{q}_{k+1}^\theta &:= \hat{q}_{k+1}^\theta - \sum_{i=1}^r \delta \bar{\eta}_{i,j}^\theta g'(y_{k+1}), \quad k = 0, \dots, N-1, \\ \delta \bar{\nu}_k^\theta &:= \delta \bar{\eta}_{i,j}^\theta(i,k) - \delta \bar{\eta}_{i,j}^\theta(i,k-1), \quad k = 0, \dots, N-1, \end{aligned} \quad (5.19)$$

We observe that \tilde{q}^θ is solution of

$$\begin{aligned} \tilde{q}_k^\theta &= \tilde{q}_{k+1}^\theta + h_k \tilde{q}_{k+1}^\theta f_y^k + h_k (v_k^\theta)^T H_{uy}^k + h_k (z_k^\theta)^T H_{yy}^k + h_k (z_k^\theta)^T g''(y_k) \\ &\quad + h_k \delta \bar{\nu}_k^\theta g'_i(y_k) - \theta h_k^2 \delta_k^p, \\ \tilde{q}_N^\theta &= (z_N^\theta)^T \phi''(y_N^\theta) + h_N \nu_N^\theta (z_N^\theta)^T g''(y_N^\theta) + h_N \delta \bar{\nu}_N^\theta g'(y_N^\theta). \end{aligned} \quad (5.20)$$

In addition, we observe that if $\delta \bar{\nu}_k^\theta \neq 0$, this means that $\delta \bar{\eta}_{i,j}^\theta(i,k) > \delta \bar{\eta}_{i,j}^\theta(i,k-1)$, and therefore that the i -th state constraint is active at step k . Since (QP) has a unique multiplier, we deduce that $\tilde{q}^\theta = q^\theta$ and $\delta \bar{\eta}^\theta = \delta \bar{\eta}_{i,j}^\theta(i,k-1)$, and

$$\delta \bar{\nu}_k^\theta = \delta \nu_k^\theta; \quad \delta \bar{\eta}_{i,j}^\theta(i,k) = \delta \eta_{i,k+1}^\theta. \quad (5.21)$$

5.2. Uniform surjectivity. We write here the *linear mappings* involved in the tangent quadratic problem, starting with

$$z_{k+1}^L = z_k^L + h_k f_y(u_k, y_k)(v_k, z_k^L), \quad k = 0, \dots, N-1; \quad z_0^L = 0. \quad (5.22)$$

For any v in the space \mathcal{V}^N , (5.22) has a unique solution denoted by $z^L[v]$. Let ξ_k be solution of $\xi_0 = 0$ and

$$\xi_{k+1} = \xi_k + h_k f_y^k \xi_k - \theta h_k^2 \delta_y^k; \quad k = 0, \dots, N-1. \quad (5.23)$$

We have that

$$z_k = z_k^L + \xi_k; \quad \|\xi\|_\infty = O(\bar{h}). \quad (5.24)$$

We set

$$\begin{aligned} \mathcal{G}_{i,j}^L(v) &:= (g'_i(y_{k_{i,j}+1}) z_{k_{i,j}+1}^L[v] - g'_i(y_{k_{i,j}}) z_{k_{i,j}}^L[v]) / \Delta t_{i,j}, \\ j &= 0, \dots, M_i^\theta - 1; \quad i = 1, \dots, r. \end{aligned} \quad (5.25)$$

The linear (homogeneous) equations corresponding to those of (QP_E) are therefore $\mathcal{G}^L(v) = 0$. Consider the following perturbation of the r.h.s. of these equations, where \bar{b} is an arbitrary r.h.s.:

$$\mathcal{G}^L(v) = \bar{b}. \quad (5.26)$$

We use the following norm, for $s \in [1, \infty)$:

$$\|\bar{b}\|_s^s := \sum_{i=1}^r \sum_{j=0}^{M_i^\theta-1} \Delta t_{i,j} |\bar{b}_{i,j}|^s. \quad (5.27)$$

These norms can be identified with the usual L^s norms on $[0, T]$ for piecewise constant functions and therefore we have the usual Cauchy-Schwarz and Hölder inequalities, in particular

$$\|\bar{b}\|_1 \leq \sqrt{rT} \|\bar{b}\|_\infty \quad (5.28)$$

PROPOSITION 5.2. *There exist constants C_s , $s \in [1, \infty]$, such that the linear equation $\mathcal{G}^L(v) = \bar{b}$ has, for small enough \bar{h} , a solution v verifying*

$$\|v\|_s \leq C_s \|\bar{b}\|_s, \quad \text{for each } s \in [1, \infty]. \quad (5.29)$$

Before proving the Proposition we introduce some notations. For $t \in [0, T]$, and $\varepsilon_0 > 0$, we define the set of ε_0 active constraints as

$$\mathcal{A}_{\varepsilon_0}(t) := \{1 \leq i \leq r; |t' - t| \leq \varepsilon_0, \text{ for some } t' \text{ such that } i \in \mathcal{A}(t')\}. \quad (5.30)$$

Since the control is continuous by **(A1)**, and the first order state constraint satisfies **(A2)**, we have that, for $\varepsilon_0 > 0$ small enough:

$$\left| \sum_{i \in \mathcal{A}_\varepsilon(t)} \lambda_i \nabla_u g_i^{(1)}(\bar{u}, \bar{y}) \right| \geq \frac{1}{2} \alpha |\lambda|, \quad \forall t \in [0, T]. \quad (5.31)$$

For $i \in \{1, \dots, r\}$ we denote the set of ε_0 active constraints by $J_{\varepsilon_0}^i$, $i = 1, \dots, r$. This is a union of closed balls (in $[0, T]$) of radius ε_0 . Since every connected component has length at least $2\varepsilon_0$, $J_{\varepsilon_0}^i$ is a finite union of closed intervals.

We next define the one-time-step analogue of \mathcal{G}^L :

$$\begin{aligned} G_{i,k}^L(v_k) &:= \frac{g'_i(y_{k+1}) z_{k+1}^L[v] - g'_i(y_k) z_k^L[v]}{h_k} \\ &= \frac{g'_i(y_{k+1}) - g'_i(y_k)}{h_k} z_k^L[v] + g'_i(y_{k+1}) (f'(u_k, y_k)(v_k, z_k^L[v])). \end{aligned} \quad (5.32)$$

Proof. [Proof of Proposition 5.2] The idea is to compute, for each k , v_k as the minimum norm solution of the linear equations

$$G_{i,k}^L(v_k) = \tilde{b}_{i,k}, \quad i \in \mathcal{A}_\varepsilon(t_k), \quad (5.33)$$

the above r.h.s. being defined later, and then to set

$$\tilde{b}_{i,k} := G_{i,k}^L(v_k), \quad \text{for } i \notin \mathcal{A}_\varepsilon(t_k). \quad (5.34)$$

Thanks to (5.31) and the expression of G_k^L , setting $z^L = z^L[v]$, we have that

$$|v_k| \leq c_1 \left(|z_k^L| + \sum_{i \in \mathcal{A}_\varepsilon(t_k)} |\tilde{b}_{i,k}| \right). \quad (5.35)$$

Here the c_i are positive constants not depending on v or k . It follows with (5.32) that

$$|\tilde{b}_k| \leq c_2 (|v_k| + |z_k^L[v]|) \leq c_3 \left(|z_k^L| + \sum_{i \in \mathcal{A}_\varepsilon(t_k)} |\tilde{b}_{i,k}| \right). \quad (5.36)$$

So, by (5.22):

$$|z_{k+1}^L| \leq (1 + c_4 h_k) |z_k^L| + c_5 h_k |v_k| \leq (1 + c_6 h_k) |z_k^L| + c_7 h_k \sum_{i \in \mathcal{A}_\varepsilon(t_k)} |\tilde{b}_{i,k}|. \quad (5.37)$$

By the discrete Gronwall's Lemma it follows that

$$\|z^L\|_\infty \leq c_8 \sum_{k=0}^{N-1} h_k \sum_{i \in \mathcal{A}_\varepsilon(t_k)} |\tilde{b}_{i,k}|, \quad (5.38)$$

and therefore, with and (5.35):

$$\|v\|_s^s \leq c_9 \sum_{k=0}^{N-1} h_k \sum_{i \in \mathcal{A}_\varepsilon(t_k)} |\tilde{b}_{i,k}|^s, \quad (5.39)$$

and in the r.h.s. we recognize the L^s norm of the ε_0 active components of \tilde{b} . We next end the proof by fixing the \tilde{b}_k in such a way that

$$\mathcal{G}_{i,k}^L(v) = \bar{b}_{i,k}; \quad \|\tilde{b}\|_s = O(\|\bar{b}\|_s). \quad (5.40)$$

We will obtain the second relation by induction over k , i.e. we will prove that there exists $c > 0$ such that

$$\sum_{\ell \leq k} |\tilde{b}_\ell|^s \leq c \sum_{i; k_{i,j} \leq k} |\bar{b}_{i,k}|^s. \quad (5.41)$$

We distinguish two cases.

a) If $\{t_{k_{i,j}}, \dots, t_{k_{i,j+1}}\} \in J_{\varepsilon_0}^i$, then take

$$\tilde{b}_{i,k} = \bar{b}_{k_{i,j+1}}, \quad k = k_{i,j} + 1, \dots, k_{i,j+1}. \quad (5.42)$$

b) If $[t_{k_{i,j}}, t_{k_{i,j+1}}] \notin J_{\varepsilon_0}^i$, let k' be the smallest index in $\{k_{i,j}, \dots, k_{i,j+1}\}$ such that $[t_{k'}, t_{k_{i,j+1}}] \in J_{\varepsilon_0}^i$. For small enough \bar{h} and ε , we must have $\text{dist}(t_{k_{i,j+1}}, J_0^i) \leq \frac{1}{2}\varepsilon_0$, and therefore

$$t_{k'} + \frac{1}{2}\varepsilon_0 \leq t_{k_{i,j+1}}. \quad (5.43)$$

We choose

$$\tilde{b}_{i,k} = \gamma, \quad k = k' + 1, \dots, k_{i,j+1}, \quad (5.44)$$

for some γ such that

$$\sum_{k=k_{i,j}+1}^{k'} h_k \tilde{b}_{i,k} + \gamma(t_{k_{i,j+1}} - t_{k'}) = (t_{k_{i,j+1}} - t_{k_{i,j}}) \bar{b}_{k_{i,j+1}}, \quad (5.45)$$

so that the first relation in (5.40) holds. At the same time, since $\frac{1}{2}\varepsilon_0 \leq t_{k_{i,j+1}} - t_{k'}$, we have that

$$\gamma \leq \frac{2}{\varepsilon_0} \left| (t_{k_{i,j+1}} - t_{k_{i,j}}) \bar{b}_{k_{i,j+1}} - \sum_{k=k_{i,j}+1}^{k'} h_k \tilde{b}_{i,k} \right| \leq \frac{2}{\varepsilon_0} \left(T |\bar{b}_{k_{i,j+1}}| + \sum_{k \leq k'} h_k |\tilde{b}_{i,k}| \right), \quad (5.46)$$

and we use the induction hypothesis (5.41) in order to estimate $\sum_{k \leq k'} h_k |\tilde{b}_{i,k}|$. The conclusion follows. \square

From the same argument of the previous result we can deduce also an estimate for the control of a feasible trajectory.

Note that

$$G_{i,k}(v_k, z_k) = G_{i,k}^L(v_k) + O(\bar{h}), \quad i = 1, \dots, r. \quad (5.47)$$

COROLLARY 5.3. *Problem (QP_E) has a feasible point \tilde{v} , such that $\|\tilde{v}\|_\infty = O(\bar{h})$.*

Proof. In view of the Proposition above, it is enough to check that we can write the active constraints of (QP_E) in the form

$$\mathcal{G}_{i,k}^L(v) = \bar{b}_{i,k}; \quad \|\bar{b}\|_\infty = O(\bar{h}). \quad (5.48)$$

Remember that $z[v] = z^L[v] + \xi_k[v]$, with $\|\xi[v]\|_\infty = O(\|v\|_1)$, and therefore

$$\begin{aligned} \bar{b}_{i,j} = & -\theta \left(\frac{g'_i(y_{k_i,j+1}) - g'_i(y_{k_i,j})}{\Delta t_{i,j}} + g'_i(y_{k_i,j+1}) f'_y(u_{k_i,j}, y_{k_i,j}) \right) \xi_{k_i,j} \\ & - \theta (h_{k+1}^2 \delta_{k+1}^g - h_k^2 \delta_k^g) / h_k, \end{aligned} \quad (5.49)$$

which is of the desired form. \square

We recall a classical consequence of the coercivity of the cost function of an equality constrained quadratic problem over its feasible set. To keep the notation as simple as it possible, we formulate the problem in an abstract way. The result will be stated with the current notation as corollary. Given two Hilbert spaces X and Y , identified with their dual, consider the optimization problem

$$\text{Min}_{x \in X} (c, x)_X + \frac{1}{2} (Hx, x)_X \quad \text{subject to} \quad Ax = b \text{ in } T, \quad (5.50)$$

where $(\cdot, \cdot)_X$ denotes the scalar product in X (et $\|\cdot\| := (\cdot, \cdot)_X$) with a similar convention for Y , $H : X \rightarrow X$ is symmetric, $A \in L(X, Y)$, $c \in X$ and $b \in Y$. The Lagrangian of the problem is

$$(c, x)_X + \frac{1}{2} (Hx, x)_X + (\lambda, Ax - b)_Y. \quad (5.51)$$

The associated optimality conditions are

$$c + Hx + A^T \lambda = 0; \quad Ax = b. \quad (5.52)$$

LEMMA 5.4. *Let $\alpha > 0$ and $c_A > 0$ be such that*

- *Coercivity: $\alpha \|x\|^2 \leq (Hx, x)_X$, for all $x \in \text{Ker } A$,*
- *Strong surjectivity: For any $b' \in Y$, there exists $x' \in A^{-1}b'$ such that $\|x'\| \leq c_A \|b'\|$.*

Then there exists $\kappa > 0$, function of α and c_A , such that (5.50) has a unique solution \bar{x} and associated Lagrange multiplier λ such that

$$\|\bar{x}\| + \|\lambda\| \leq \kappa (\|b\| + \|c\|). \quad (5.53)$$

Proof. That (5.50) has a unique solution \bar{x} is an easy consequence of the coercivity (which in the case of a quadratic cost implies the strong convexity over the feasible

set since the latter is a vector subspace). The uniqueness of the Lagrange multiplier λ is consequence of the surjectivity of A , implied by hypothesis (ii).

The latter also implies the existence of x^0 such that $Ax^0 = b$ and $\|x^0\| \leq c_A\|b\|$. Then $\delta x := \bar{x} - x^0$ is solution of

$$H\delta x + A^T\lambda = -c - Hx^0; \quad A\delta x = 0. \quad (5.54)$$

Therefore, since $\delta x \in \text{Ker } A$:

$$\alpha\|\delta x\|^2 \leq \delta x^T H\delta x = -(\delta x, c + Hx^0)_X + (A\delta x, \lambda),$$

so that $\|\delta x\| \leq (\|c\| + \|Hx^0\|)/\alpha$. Since $\|x^0\| \leq c_A\|b\|$, we deduce that

$$\|\bar{x}\| \leq \|\delta x\| + \|x^0\| \leq c_A\|b\| + \frac{1}{\alpha}(\|c\| + \|H\|c_A\|b\|). \quad (5.55)$$

By the surjectivity hypothesis

$$\|\lambda\| \leq \frac{1}{c_A}\|A^T\lambda\| \leq \frac{1}{c_A}(\|c\| + \|H\|\|x\|), \quad (5.56)$$

The conclusion follows. \square

We apply the previous result to (QP_E) using the following Lemma, where $\bar{v} := v^1$:

LEMMA 5.5. *We have that*

$$|\Omega^\theta(v) - \Omega(\bar{v})| = O(\varepsilon\|\bar{v}\|)^2.$$

Proof. Since for definition (2.22) $h_k\nu_k = \bar{\eta}_k - \bar{\eta}_{k+1}$ it follows that, using the fact that $\nu_0 = \nu_N = 0$:

$$\begin{aligned} \Delta &:= \sum_{k=0}^N h_k\nu_k D^2 g_k^\theta(z_k)^2 = \sum_{k=0}^N (\bar{\eta}_k - \bar{\eta}_{k+1}) D^2 g_k^\theta(z_k)^2 \\ &= \sum_{k=1}^{N-1} \bar{\eta}_k (D^2 g_k^\theta(z_k)^2 - D^2 g_{k-1}^\theta(z_{k-1})^2) = \Delta_1 + \Delta_2, \end{aligned}$$

where by a Taylor expansion of $D^2 g^\theta$, for some $\hat{y}_k \in [y_{k-1}, y_k]$:

$$\begin{aligned} \Delta_1 &:= \sum_{k=1}^{N-1} \bar{\eta}_k (D^2 g_k^\theta(z_k)^2 - D^2 g_{k-1}^\theta(z_k)^2) \\ &= \sum_{k=1}^{N-1} h_k \bar{\eta}_k D^3 g^\theta(\hat{y}_k)(f_{k-1}^\theta, z_k, z_k), \end{aligned}$$

using the identity $A(b, b) - A(a, a) = A(a + b, a - b)$ for any symmetric bilinear form A , and the linearized state equation

$$\begin{aligned} \Delta_2 &:= \sum_{k=1}^{N-1} \bar{\eta}_k (D^2 g_{k-1}^\theta(z_k)^2 - D^2 g_{k-1}^\theta(z_{k-1})^2) \\ &= \sum_{k=1}^{N-1} h_{k-1} \eta_k D^2 g_{k-1}^\theta(z_k + z_{k-1}, Df_{k-1}^\theta(v_{k-1}, z_{k-1})). \end{aligned}$$

We deduce that, for \bar{h} small enough,

$$\Delta_1 = \int_0^T g^{(3)}(\bar{y}(t))(f[t], \bar{z}(t), \bar{z}(t))\bar{\eta}(t)dt + O(\varepsilon\|\bar{v}\|)$$

and

$$\Delta_2 = 2 \int_0^T g''(\bar{y}(t))(\bar{z}(t), f_y[t](\bar{z}(t), \bar{v}(t))\bar{\eta}(t)dt + O(\varepsilon\|\bar{v}\|).$$

Using the identity (2.19) we can claim that $|\Omega^\theta(v) - \tilde{\Omega}(\bar{v})| = O(\varepsilon\|\bar{v}\|)^2$. We conclude with Lemma 2.3. \square

COROLLARY 5.6. *Let assumptions (A0)-(A3) hold as well as either (A4) or (A5). We have that (QP_E) has a unique solution v^θ associated with a unique alternative multiplier $\delta\bar{\eta}^\theta$, and they satisfy*

$$\|v^\theta\|_2^2 + \|\delta\bar{\eta}^\theta\|_2^2 = O(\bar{h}). \quad (5.57)$$

Proof. The surjectivity of the constraint condition was proved in Proposition 5.2. If (A4) holds, then the coercivity property is an easy consequence of the stability after discretization of the Hessian of the Lagrangian (Lemma 5.5 above) and of the solution of the linearized state equation. If (A5) holds, the coercivity property is derived in Appendix A. \square

5.3. Estimate of the directional derivative. We arrive, finally, to the main result of the Section. We recall that $\delta X^\theta := (v^\theta, z^\theta, q^\theta, \delta\eta^\theta)$ is the directional derivative (on the left) of $X^\theta := (u^\theta, y^\theta, p^\theta, \eta^\theta)$.

PROPOSITION 5.7. *We have, for a fixed $C > 0$*

$$\|v^\theta\|_\infty + \|z^\theta\|_\infty + \|q^\theta\|_\infty + \|\delta\eta^\theta\|_\infty \leq C\bar{h}.$$

Proof. (a) Applying Lemma 5.4 to (QP_E) , where X and Y have norms defined by (5.29) (where $s = 2$) and (5.27), having in mind that, by the definition of the Lagrangian, we have identified the image space (of b^E) with its dual, we get that that

$$\|v^\theta\|_2 + \sum_{i,j} \Delta t_{i,j} |\delta\bar{\eta}_{i,j}^\theta|^2 \leq c_1\bar{h}. \quad (5.58)$$

Fix $\varepsilon_\eta > 0$, not depending on \bar{h} . Then

$$\text{If } \Delta t_{i,j} > \varepsilon_\eta, \text{ then } |\delta\bar{\eta}_{i,j}^\theta| \leq c_1\varepsilon_\eta^{-1/2}\bar{h}. \quad (5.59)$$

So, as far as $\delta\bar{\eta}^\theta$ is concerned, it remains to obtain a uniform estimate when $\Delta t_{i,j} \leq \varepsilon_\eta$. It easily follows from (5.58), the linearized state equation (5.2), and the linearized costate equations (5.17) that

$$\|z^\theta\|_\infty + \|q^\theta\|_\infty \leq c_2\bar{h}. \quad (5.60)$$

(b) By (5.7), $|\bar{b}_{i,j}| = O(\bar{h})$. Evaluating the contribution of the term containing z_k , observing $\sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k = \Delta t_{i,j}$ and then

$$\frac{1}{\Delta t_{i,j}} \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k \nabla_u \hat{g}_{i,k}^{(1)} v_k = O(\bar{h}). \quad (5.61)$$

Eliminating v_k in (5.18)(i), we get

$$\frac{1}{\Delta t_{i,j}} \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k \nabla_u \hat{g}_{i,k}^{(1)} (H_{uu}^k)^{-1} \sum_{i'=1}^r (\nabla_u \hat{g}_{i',k}^{(1)})^T \delta \bar{\eta}_{i',j(i',k)}^\theta = O(\bar{h}). \quad (5.62)$$

Multiplying by $\delta \bar{\eta}_{i,j(i,k)}^\theta$ on the left, summing over i and $j \in I_{i',k}$ and setting

$$w_k := \sum_{i=1}^r (\nabla_u \hat{g}_{i,k}^{(1)})^T \delta \bar{\eta}_{i,j(i,k)}^\theta \quad (5.63)$$

we get

$$\frac{1}{\Delta t_{i,j}} \sum_{i=1}^r \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k w_k^T (H_{uu}^k)^{-1} w_k = O(\bar{h}) |\delta \bar{\eta}^\theta|. \quad (5.64)$$

Denote by $\hat{\eta}$ the vector of components $\delta \bar{\eta}_{i,j(i,k)}^\theta$, for $i = 1$ to r . For small enough ε depending on $\hat{\eta}$, by **(A2)**-**(A3)**, we have that

$$|\hat{\eta}|^2 \leq \alpha_g^2 |w_k|^2 \leq \alpha^{-1} \alpha_g^2 w_k^T (H_{uu}^k)^{-1} w_k \quad (5.65)$$

and therefore, since $\Delta t_{i,j} = \sum_{k=k_{i,j}+1}^{k_{i,j}+1} h_k$:

$$|\hat{\eta}|^2 \leq \frac{\alpha^{-1} \alpha_g^2}{\Delta t_{i,j}} \sum_{k=k_{i,j}+1}^{k_{i,j}+1} w_k^T (H_{uu}^k)^{-1} w_k = O(\bar{h}) |\hat{\eta}|. \quad (5.66)$$

Therefore, we get with (5.21) that

$$|\delta \bar{\eta}_{i,j(i,k)}^\theta| \leq O(\bar{h}). \quad (5.67)$$

The corresponding estimate for v^k and $\delta \eta^\theta$ follow from (5.18) and (5.21). \square

6. Example. We will present here an easy example taken from [15]. Let us consider the following optimal control problem, where $g := 9.8$:

$$\begin{aligned} & \text{Min } \int_0^1 \left(\frac{1}{2} u^2(t) + g y(t) \right) dt \\ & \text{s.t. } \dot{y}(t) = u(t), \quad y(0) = y(1) = 1, \quad y(t) \geq 0, \end{aligned}$$

The solution of this problem can be seen as the minimum energy state of a system composed by a rope of uniformly distributed mass in a constant gravity field, with the presence of a lower constraint (for example a table). We may apply our results by viewing t as a component of the state.

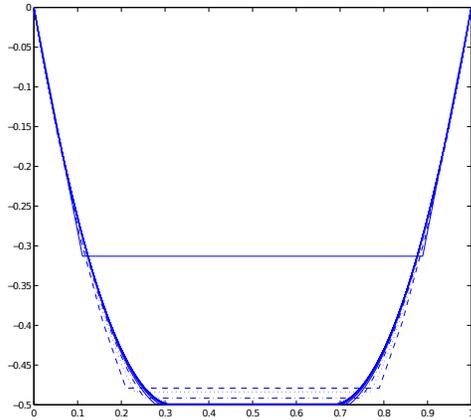

FIG. 6.1. Test with various discrete steps.

We solved the discrete solution using a shooting method; in Figure 6 and Table 6 are shown the results at various constant discrete steps h . This test confirms the convergence results stated before.

Appendix A. Analysis of assumption (A5).

As shown before, a key point of the theory is the coercivity of the (QP) . Under the assumptions (A5), we can obtain it directly showing the stability of the boundary arcs. This will be sufficient to guarantee the coercivity of the Hessian of the Lagrangian. A main point is contained in the following Lemma:

LEMMA A.1. *Let (A0) – (A3) and (A5) hold. Given a boundary arc (t_a, t_b) , let k_a and k_b be defined as*

$$k_a \text{ (resp. } k_b\text{): first index (resp. last index) for which } t_k > t_a \text{ (resp. } t_k < t_b\text{). (A.1)}$$

Let $\varepsilon' > 0$. Reducing $\varepsilon > 0$ small enough, we have that when \bar{h} is small enough, the following holds:

$$g(y_k^\theta) = 0, \text{ for all } 0 \leq k \leq N \text{ such that } t_{k_a} + \varepsilon' < t_k < t_{k_b} - \varepsilon'.$$

Proof. (a) By the definition $\|\eta^\theta - \bar{\eta}\|_\infty < \varepsilon$, and by **(A5)**, $\bar{\eta}$ has a uniformly positive derivative over $(t_{k_a} + \varepsilon' < t_k < t_{k_b} - \varepsilon')$ minorized by $c_1 > 0$. We have that for $k_a < k < k_b$:

$$\eta_k^\theta \geq \bar{\eta}(t_k) - \varepsilon \geq \bar{\eta}(t_{k_a}) + c_1(t_k - t_{k_a}) - \varepsilon \geq \eta_{k_a}^\theta + c_1(t_k - t_{k_a}) - 2\varepsilon, \quad (\text{A.2})$$

that is,

$$c_1(t_k - t_{k_a}) - 2\varepsilon \leq \eta_k^\theta - \eta_{k_a}^\theta. \quad (\text{A.3})$$

Therefore, if $t_k - t_{k_a} > 2\varepsilon/c_1$, the above r.h.s. must be positive, proving that the constraint is active for some k such that $t_k \leq t_{k_a} + 2\varepsilon/c_1$.

(b) If the conclusion does not hold, by step (a), it suffices to prove that $g(y_k^\theta)$ cannot have a negative local minimum for some $k_a < k < k_b$. We give a proof by contradiction. If this was the case, then $\Delta_g^k \geq 0$, defined in (4.6), and $\nu_k = 0$. Multiplying (4.3) by $\nabla_u g^{(1)}(u_k, y_k)^T \mathcal{H}_k^{-1}$ on the left and using Lemma 4.1(ii) and (4.8), we get

$$-\frac{\Delta_g^k}{h_k} + \nu_k (\nabla_u g^{(1)}(u_k, y_k))^T \mathcal{H}_k^{-1} \nabla_u g^{(1)}(u_k, y_k) = \hat{\Xi}_k^\theta, \quad (\text{A.4})$$

where $\hat{\Xi}_k^\theta$ is such that $\|\hat{\Xi}^\theta - \hat{\Xi}^1\|_\infty = O(\varepsilon)$. We have that the l.h.s. of (A.4) is greater than a positive constant independent on \bar{h} , since, for $\theta = 1$, for some $K > 0$, $\Delta_g^k = 0$, $\nu_k > K$ and $|\nabla_u g^{(1)}| > K$, i.e.,

$$-\frac{\Delta_g^k}{h_k} + \nu_k (\nabla_u g^{(1)}(u_k, y_k))^T \mathcal{H}_k^{-1} \nabla_u g^{(1)}(u_k, y_k) \geq C. \quad (\text{A.5})$$

This relation is still valid for ε and \bar{h} small enough, for all $\theta \in [\theta_m, 1]$, in view of the continuity of the r.h.s. of (A.4). However, if a negative minimum of the state constraint is attained at index k , then $\nu_k = 0$ and $\Delta_g^k \geq 0$, contradicting (A.5). \square

Here we prove the coercivity of Ω^θ over the feasible domain of (QP) . Note that such a property is naturally preserved passing to the alternative formulation $\tilde{\Omega}^\theta$ as shown, for the continuous case in Section 2.

LEMMA A.2. *Let **(A5)** hold. Then Ω^θ is uniformly coercive over the feasible domain of (QP) .*

Proof. (a) We first examine the continuous problem and prove that Ω is, for $\varepsilon > 0$ small enough, coercive over the following enlargement of the critical cone:

$$C_\varepsilon := \{v \in \mathcal{V} \mid g_k = 0, \text{ for all } 0 \leq k \leq N \text{ such that } t_{k_a} + \varepsilon < t_k < t_{k_b} - \varepsilon\}. \quad (\text{A.6})$$

Indeed, otherwise we would have a sequence $\varepsilon_q \downarrow 0$ and v^q in C_{ε_q} such that $\Omega(v^q) \leq o(1)$. Extracting if necessary a subsequence, assume that v^q weakly converges to \bar{v} in \mathcal{V} . Thanks to the Legendre condition we have that Ω is a Legendre form and therefore

$$\Omega(\bar{v}) \leq \liminf_{q \rightarrow 0} \Omega(v^q) \leq 0. \quad (\text{A.7})$$

At the same time; by standard compactness arguments $g'(\bar{y})\bar{z} = 0$ when the constraint is active (where \bar{z} is the linearized state associated with \bar{v}), and so, \bar{v} is a critical

direction. So, $\Omega(\bar{v}) \leq 0$ implies that $\bar{v} = 0$. But then $\Omega(\bar{v}) = \lim_q \Omega(v^q)$, so that v^q (of unit norm) strongly converges to \bar{v} , which gives the desired contradiction.

(b) Now let v belong to the feasible domain of (QP) . By Lemma A.1, we know that v belongs to the set

$$\{v \in \mathcal{V}^N; |g'(y_k^\theta)z_k| \leq \varepsilon, 0 \leq k \leq N \text{ such that } t_{k_a} + \varepsilon < t_k < t_{k_b} - \varepsilon.\}. \quad (\text{A.8})$$

Let \bar{v} be the associated element of \mathcal{V} and \bar{z} the corresponding linearized state. Given $\varepsilon > 0$, it is easily checked that $\bar{v} \in C_\varepsilon$ when \bar{h} is small enough, and so, by step (a), $\Omega(\bar{v}) \geq \frac{1}{2}\alpha\|\bar{v}\|^2$. We conclude with Lemma 5.5. \square
