September 5, 2017 (revised Dec 12, 2018)

Abstract

In the present paper, we prove that the augmented Lagrangian method converges to KKT points under the quasinormality constraint qualification, which is associated with the external penalty theory. An interesting consequence is that the Lagrange multipliers estimates computed by the method remain bounded in the presence of the quasinormality condition. In order to establish a more general convergence result, a new sequential optimality condition for smooth constrained optimization, called PAKKT, is defined. The new condition takes into account the sign of the dual sequence, constituting an adequate sequential counterpart to the (enhanced) Fritz-John necessary optimality conditions proposed by Hestenes, and later extensively treated by Bertsekas. PAKKT points are substantially better than points obtained by the classical Approximate KKT (AKKT) condition, which has been used to establish theoretical convergence results for several methods. In particular, we present a simple problem with complementarity constraints such that all its feasible points are AKKT, while only the solutions and a pathological point are PAKKT. This shows the efficiency of the methods that reach PAKKT points, particularly the augmented Lagrangian algorithm, in such problems. We also provided the appropriate strict constraint qualification associated with the PAKKT sequential optimality condition, called PAKKT-regular, and we prove that it is strictly weaker than both quasinormality and cone continuity property. PAKKT-regular connects both branches of these independent constraint qualifications, generalizing all previous theoretical convergence results for the augmented Lagrangian method in the literature.

Key words: Augmented Lagrangian methods, global convergence, constraint qualifications, quasinormality, sequential optimality conditions.

1 Introduction

We will consider the general constrained nonlinear problem

$$\min_x f(x) \text{ subject to } x \in X \tag{P}$$

where $f : \mathbb{R}^n \rightarrow \mathbb{R}$ and X is the feasible set composed of equality and inequality constraints of the form

$$X = \{x \mid h(x) = 0, g(x) \leq 0\},$$

with $h : \mathbb{R}^n \rightarrow \mathbb{R}^m$ and $g : \mathbb{R}^n \rightarrow \mathbb{R}^p$. We assume that the functions f , h and g are continuously differentiable in \mathbb{R}^n . Given $x^* \in X$ we denote by $I_g(x^*) = \{j \in \{1, \dots, p\} \mid g_j(x^*) = 0\}$ the set of active inequality constraints at x^* .

Several of the more traditional nonlinear programming methods are iterative: given an iterate x^k , they try to find a better approximation x^{k+1} of the solution. In this paper we consider the augmented Lagrangian method, a popular technique in constrained optimization. The classical augmented Lagrangian method uses an iterative sequence of subproblems considerably easier to solve. In each subproblem, fixed a penalty parameter $\rho > 0$ and Lagrange multiplier estimates $\lambda \in \mathbb{R}^m$ and $\mu \in \mathbb{R}^p$, $\mu \geq 0$, an augmented Lagrangian function is approximately minimized. Once the approximate solution is found, the penalty parameter ρ and the multipliers estimates are updated, and a new iteration starts. Specifically, we consider the Powell-Hestenes-Rockafellar (PHR) augmented Lagrangian function that, for the problem (P), takes the form

$$L_\rho(x, \lambda, \mu) = f(x) + \frac{\rho}{2} \left(\sum_{i=1}^m \left(h_i(x) + \frac{\lambda_i}{\rho} \right)^2 + \sum_{j=1}^p \max \left\{ 0, g_j(x) + \frac{\mu_j}{\rho} \right\}^2 \right), \quad (1)$$

where $x \in \mathbb{R}^n$, $\rho > 0$, $\lambda \in \mathbb{R}^m$ and $\mu \in \mathbb{R}^p$, $\mu \geq 0$. This is the most widely used augmented Lagrangian function in practical implementations (see [14] for a numerical comparison between several of them). However, other functions were also employed, see for example [11, 18] and references therein. The choice of (1) is justified by its intrinsic relation to the external penalty theory, where the quasinormality, a very general constraint qualification proposed by Hestenes [22], plays an important role. This is the central issue in this work.

In the last years, special attention has been devoted to so-called sequential optimality conditions for nonlinear constrained optimization (see for example [3, 7, 9, 8, 15, 25]). They are related to the stopping criteria of algorithms, and aim to unify their theoretical convergence results. In particular, they have been used to study the convergence of the augmented Lagrangian method (see [15] and references therein). An important feature of sequential optimality conditions is that they are necessary for optimality: a local minimizer of (P) verifies such a condition independently of the fulfillment of any constraint qualification. One of the most popular sequential optimality condition is the *Approximate Karush-Kuhn-Tucker* (AKKT) condition, defined in [3]. We say that $x^* \in X$ satisfies the AKKT condition if there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}^p$, $\mu^k \geq 0$, such that

$$\lim_{k \rightarrow \infty} x^k = x^*, \quad (2a)$$

$$\lim_{k \rightarrow \infty} \|\nabla_x L(x^k, \lambda^k, \mu^k)\| = 0, \quad (2b)$$

$$\lim_{k \rightarrow \infty} \|\min\{-g(x^k), \mu^k\}\| = 0, \quad (2c)$$

where $L(\cdot)$ is the usual Lagrangian function associated with (P). Such kind of points x^* will be called AKKT points and $\{x^k\}$ an AKKT sequence.

Of course, when it is proved that an AKKT point is in fact a KKT point under a certain constraint qualification (CQ), all the algorithms that reach AKKT points, such as the augmented Lagrangian method [15], have their theoretical convergence automatically established with the same CQ (this is exactly what we mean when we say that a sequential optimality condition unifies convergence results). During the last years, it has been proved that AKKT points are stationary points under different constraint qualifications such as the *constant positive linear dependence* (CPLD) [6, 27], the *relaxed constant positive linear dependence* (RCPLD) [4] and the *constant positive generator* (CPG) [5]. Finally, it was shown that the *cone continuity property* (CCP) (also called AKKT-regular CQ [9]) is the least stringent constraint qualification with this property [8]. All these CQs deal with rank and/or positive linear dependence assumptions. Pseudonormality and quasinormality CQs [22, 12], on the contrary, have a different nature. They impose a control on the multipliers around the point of interest. In this paper we define a new constraint qualification, called *PAKKT-regular*, that unifies both types of such CQs. In other words, we prove that PAKKT-regular is strictly weaker than both quasinormality and CCP. See Figure 4. The interest in this new CQ is that it is associated with the convergence of a practical augmented Lagrangian method, as we will discuss later.

Despite the clear similarities between the PHR augmented Lagrangian and the pure external penalty methods, an interesting topic that still unsolved is the convergence of the augmented Lagrangian method under the quasinormality CQ. The authors of [8] show that CCP has no relation with quasinormality or, in particular, that there are examples where quasinormality and the AKKT condition hold but KKT does not. In this sense, it is not possible to answer the proposed question using only the AKKT condition. Indeed, it is surprising to note that the PHR augmented Lagrangian method, which uses the quadratic penalty-like function (1), naturally generates AKKT points while it is not trivial to understand how it handles the sign of the multipliers, as performed by the external penalty method.

In the present paper we address the previous question by proving that the PHR augmented Lagrangian method converges under the new PAKKT-regular CQ (and, consequently, under quasinormality). To the best of our knowledge, this is the first time it has been proved that a practical algorithm converges under quasinormality. Particularly, we show that their feasible accumulation points are in fact stronger than AKKT points. We call these points *Positive Approximate Karush-Kuhn-Tucker* (PAKKT), for which PAKKT-regular is the least stringent associated constraint qualification that ensures KKT. More generally, the theoretical convergence of every method that generate AKKT points can be improved if we are able to show that the method actually generate PAKKT points. As an illustration, let us consider the problem

$$\min_x (x_1 - 1)^2 + (x_2 - 1)^2 \quad \text{subject to} \quad x_1, x_2 \geq 0, \quad x_1 x_2 \leq 0, \quad (3)$$

for which $(1, 0)$ and $(0, 1)$ are the unique solutions. We affirm that every feasible point \bar{x} is AKKT. In fact, we can suppose without loss of generality that $\bar{x}_2 = 0$. If $\bar{x}_1 > 0$ then it is straightforward to verify that \bar{x} is an AKKT point with the sequences defined by $x^k = (\bar{x}_1, 2(1 - \bar{x}_1)/k)$ and $\mu^k = (0, k\bar{x}_1 - 2, k)$ for all $k \geq 2/\bar{x}_1$. If $\bar{x}_1 = 0$, it is sufficient to take $x^k = (2/k, 2/k)$ and $\mu^k = (0, 0, k)$ for all $k \geq 1$. However, only $(1, 0)$, $(0, 1)$ and $(0, 0)$ are PAKKT points because, particularly, all feasible points, excluding the origin, satisfy the quasinormality CQ. Thus, while a pure ‘‘AKKT method’’ may reaches any point, a method that ensures convergence to PAKKT points will avoid most of the undesirable ones. Problem (3) belongs to the class of *Mathematical Programs with Complementarity Constraints* (MPCC). We make further comments about these problems in section 4.1, revisiting and extending previously known results about the convergence of augmented Lagrangian methods [10, 23]. Furthermore, we prove that the sequence of Lagrange multipliers estimates generated by the method applied to the general problem (P) is bounded whenever the quasinormality condition holds at the accumulation point. This is particularly true for MPCCs under the so-called MPCC-quasinormality CQ.

The key to define the PAKKT condition is to take into account the sign of Lagrange multipliers as in the Fritz-John necessary conditions described in [12] (see also [22]). Specifically, we rely on the following result:

Theorem 1.1 ([12, Proposition 3.3.5]). *Let x^* be a local minimizer of the problem (P). Then there are $\sigma \in \mathbb{R}_+$, $\lambda \in \mathbb{R}^m$ and $\mu \in \mathbb{R}^p$, $\mu \geq 0$, such that*

1. $\sigma \nabla f(x^*) + \sum_{i=1}^m \lambda_i \nabla h_i(x^*) + \sum_{j=1}^p \mu_j \nabla g_j(x^*) = 0$;
2. $(\sigma, \lambda, \mu) \neq 0$;
3. *In every neighborhood $\mathcal{B}(x^*)$ of x^* there is an $x \in \mathcal{B}(x^*)$ such that $\lambda_i h_i(x) > 0$ for all i with $\lambda_i \neq 0$ and $\mu_j g_j(x) > 0$ for all j with $\mu_j > 0$.*

We will refer to Theorem 1.1 by enhanced Fritz-John (necessary) conditions. We call a point x^* that fulfills all the three items of Theorem 1.1 by an *Enhanced Fritz-John* (EFJ) point. We note that an EFJ point is a KKT point whenever $\sigma > 0$. Conditions (1.) and (2.) symbolize the classical Fritz-John result about stationary points. Condition (3.) stands for the existence of sequences which connect the sign of the multiplier with the sign of the associated constraint in a neighborhood of the stationary point. Enhanced Fritz-John conditions were used previously to generalize some classical results [13, 31].

This paper is organized as follows. In section 2 we describe the new sequential optimality condition PAKKT and its associated strict constraint qualification PAKKT-regular. In section 3 we establish the relationship between PAKKT and other sequential optimality conditions in the literature. Relations of

PAKKT-regular with other known constraint qualifications are also included in section 3. In section 4 we present the global convergence of the augmented Lagrangian method using the PAKKT-regular CQ. The strength of the PAKKT condition is discussed in section 4.1, and the boundedness of the dual sequences generated by the augmented Lagrangian method is treated in section 4.2. Conclusions and lines for future research are given in section 5.

Notation:

- $\mathbb{R}_+ = \{t \in \mathbb{R} \mid t \geq 0\}$, $\|\cdot\|$ denotes an arbitrary vector norm, $\|\cdot\|_\infty$ the supremum norm and $\|\cdot\|_2$ the Euclidean norm.
- v_i is the i -th component of the vector v .
- For all $y \in \mathbb{R}^n$, $y_+ = (\max\{0, y_1\}, \dots, \max\{0, y_n\})$.
- If $K = \{k_0, k_1, k_2, \dots\} \subset \mathbb{N}$ ($k_{j+1} > k_j$), we denote $\lim_{k \in K} y^k = \lim_{j \rightarrow \infty} y^{k_j}$. In particular, $\lim_k y^k = \lim_{k \in \mathbb{N}} y^k$.
- If $\{\gamma_k\} \subset \mathbb{R}$, $\gamma_k > 0$ and $\gamma_k \rightarrow 0$, we write $\gamma \downarrow 0$.
- We define the “sign function” $\operatorname{sgn} a$ putting $\operatorname{sgn} a = 1$ if $a > 0$ and $\operatorname{sgn} a = -1$ if $a < 0$. We have $\operatorname{sgn}(a \cdot b) = \operatorname{sgn} a \cdot \operatorname{sgn} b$.

2 The positive approximate Karush-Kuhn-Tucker condition

In this section we define the positive approximate Karush-Kuhn-Tucker condition and we show that it is a genuine necessary optimality condition.

Definition 2.1. *We say that $x^* \in X$ is a Positive Approximate KKT (PAKKT) point if there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}_+^p$ such that*

$$\lim_k x^k = x^*, \tag{4}$$

$$\lim_k \|\nabla_x L(x^k, \lambda^k, \mu^k)\| = 0, \tag{5}$$

$$\lim_k \|\min\{-g(x^k), \mu^k\}\| = 0, \tag{6}$$

$$\lambda_i^k h_i(x^k) > 0 \text{ if } \lim_k \frac{|\lambda_i^k|}{\delta_k} > 0, \tag{7}$$

$$\mu_j^k g_j(x^k) > 0 \text{ if } \lim_k \frac{\mu_j^k}{\delta_k} > 0, \tag{8}$$

where $\delta_k = \|(1, \lambda^k, \mu^k)\|_\infty$. In this case, $\{x^k\}$ is called a PAKKT sequence.

The expressions (4) to (6) are related to the KKT conditions, and they are used in the Approximate KKT (AKKT) optimality condition presented in the introduction. The expressions (7) and (8) aim to control the sign of Lagrange multipliers, justifying the name of our new condition. They are related to the enhanced Fritz-John necessary optimality conditions described in the introduction (Theorem 1.1). We will see that (7) and (8) give an adequate counterpart for the third item of Theorem 1.1 in the sequential case. As always $|\lambda_i^k|/\delta_k, \mu_j^k/\delta_k \in [0, 1]$ we can suppose, taking a subsequence if necessary, that these limits exist. It is important to note that item (3.) of Theorem 1.1 is sufficient for complementary slackness, but the sequential counterpart (7) and (8) is not. The next example shows that the complementary slackness at the limit x^* may fail without condition (6) if $\{\delta_k\}$ is unbounded.

Example 2.1. *Let us consider the problem*

$$\min_x -x_1 + x_2 \quad \text{subject to} \quad x_2^2 = 0, \quad x_1 - 1 \leq 0,$$

for which

$$\nabla_x L(x, \lambda, \mu) = \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \lambda \begin{bmatrix} 0 \\ 2x_2 \end{bmatrix} + \mu \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

The point $x^* = (0, 0)$ satisfies (4), (5), (7) and (8) with, for example, the sequences defined by $x^k = (0, -1/k)$, $\lambda^k = k/2$ and $\mu^k = 1$ for all $k \geq 1$. In fact, we have $x^k \rightarrow (0, 0)$, $\nabla_x L(x^k, \lambda^k, \mu^k) = 0$, $\lambda^k (x_2^k)^2 = 1/(2k) > 0$ with $\lim_k |\lambda^k|/\delta_k = 1$, and $\lim_k \mu^k/\delta_k = 0$. But, taking a subsequence if necessary, any sequence satisfying (4), (5), (7) and (8) is such that $|\lambda^k| \rightarrow \infty$ and $\mu^k \rightarrow 1$. Thus $\lim_k \mu^k/\delta_k = 0$, but $\min\{-(x_1^k - 1), \mu^k\} \rightarrow 1$.

Theorem 2.1. *PAKKT is a necessary optimality condition.*

Proof. Let x^* be a local minimizer of (P). Then x^* is the unique global minimizer of the problem

$$\min_x f(x) + 1/2 \|x - x^*\|_2^2 \quad \text{subject to} \quad h(x) = 0, \quad g(x) \leq 0, \quad \|x - x^*\| \leq \alpha$$

for a certain $\alpha > 0$. Let x^k be a global minimizer of the penalized problem

$$\min_x f(x) + 1/2 \|x - x^*\|_2^2 + \frac{\rho_k}{2} [\|h(x)\|_2^2 + \|g(x)_+\|_2^2] \quad \text{subject to} \quad \|x - x^*\| \leq \alpha,$$

$\rho_k > 0$, which exists by the continuity of the objective function and compactness of the feasible set. We suppose that $\rho_k \rightarrow \infty$. From the external penalty theory, $x^k \rightarrow x^*$ and thus (4) is satisfied. We have $\|x^k - x^*\| < \alpha$ for all k sufficiently large (let us say for all $k \in K$), and from optimality conditions of the penalized problem we obtain

$$\lim_{k \in K} \nabla_x L(x^k, \lambda^k, \mu^k) = \lim_{k \in K} [\nabla f(x^k) + \nabla h(x^k) \lambda^k + \nabla g(x^k) \mu^k] = - \lim_{k \in K} (x^k - x^*) = 0,$$

where, for each $k \in K$,

$$\lambda^k = \rho_k h(x^k) \quad \text{and} \quad \mu^k = \rho_k g(x^k)_+ \geq 0.$$

Therefore (5) and (6) are satisfied. If $\mu_i^k > 0$, $k \in K$, then $g_i(x^k) > 0$ and hence $\mu_i^k g_i(x^k) = \rho_k [g_i(x^k)]^2 > 0$. Analogously, if $\lambda_i^k \neq 0$, $k \in K$, then $h_i(x^k) \neq 0$ and hence $\lambda_i^k h_i(x^k) = \rho_k [h_i(x^k)]^2 > 0$. Thus (7) and (8) are fulfilled, independently of the limits of the dual sequences. \square

We say that SCQ is a *strict constraint qualification* for the sequential optimality condition A if

$$\text{A} + \text{SCQ} \text{ implies KKT}$$

(see [15]). Since all sequential optimality conditions are satisfied in any local minimizer independently of fulfillment of CQs, a SCQ is in fact a constraint qualification. The reciprocal is not true. For instance, Abadie's CQ [1] or quasnormality [22] are CQs that are not SCQs for the AKKT sequential optimality condition. On the other hand, the strict constraint qualification SCQ provides a measure of the quality of the sequential optimality condition A. Specifically, A is better as SCQ is less stringent (weaker). In [8], the authors presented the weakest strict constraint qualification associated with AKKT, called *Cone Continuity Property* (CCP). Recently [9], CCP was renamed to "AKKT-regular" and the weakest SCQs related to SAKKT [21], CAKKT [7] and AGP [25] conditions were established.

In this section, we provide the weakest SCQ for PAKKT condition, which we call PAKKT-regular. For this purpose, we define for each $x^* \in X$ and $x \in \mathbb{R}^n$, $\alpha, \beta \geq 0$, the set

$$K_+(x, \alpha, \beta) = \left\{ \sum_{i=1}^m \lambda_i \nabla h_i(x) + \sum_{j \in I_g(x^*)} \mu_j \nabla g_j(x) \left| \begin{array}{l} \lambda_i h_i(x) \geq \alpha \text{ if } |\lambda_i| > \beta \|(1, \lambda, \mu)\|_\infty \\ \mu_j g_j(x) \geq \alpha \text{ if } \mu_j > \beta \|(1, \lambda, \mu)\|_\infty \\ \lambda \in \mathbb{R}^m, \quad \mu_j \in \mathbb{R}_+, \quad j \in I_g(x^*) \end{array} \right. \right\}.$$

Note that the KKT conditions for (P) can be written as $-\nabla f(x^*) \in K_+(x^*, 0, 0)$.

Given a multifunction $\Gamma : \mathbb{R}^s \rightrightarrows \mathbb{R}^q$, the *sequential Painlevé-Kuratowski outer/upper limit* of $\Gamma(z)$ as $z \rightarrow z^*$ is denoted by

$$\limsup_{z \rightarrow z^*} \Gamma(z) = \{y^* \in \mathbb{R}^q \mid \exists(z^k, y^k) \rightarrow (z^*, y^*) \text{ with } y^k \in \Gamma(z^k)\} \quad (9)$$

[28]. We say that Γ is *outer semicontinuous* at z^* if $\limsup_{z \rightarrow z^*} \Gamma(z) \subset \Gamma(z^*)$. We define the PAKKT-regular condition imposing an outer semicontinuity-like on the multifunction $(x, \alpha, \beta) \in \mathbb{R}^n \times \mathbb{R}_+ \times \mathbb{R}_+ \rightrightarrows K_+(x, \alpha, \beta)$. Analogously to (9), we consider the following set:

$$\limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta) = \{y^* \in \mathbb{R}^n \mid \exists(x^k, y^k) \rightarrow (x^*, y^*), \alpha_k \downarrow 0, \beta_k \downarrow 0 \text{ with } y^k \in K_+(x^k, \alpha_k, \beta_k)\}.$$

Definition 2.2. We say that $x^* \in X$ satisfies the PAKKT-regular condition if

$$\limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta) \subset K_+(x^*, 0, 0).$$

Next we prove the main result of this section, which guarantees that PAKKT-regular is the weakest SCQ for the PAKKT sequential optimality condition.

Theorem 2.2. *If x^* is a PAKKT point that fulfills the PAKKT-regular condition then x^* is a KKT point. Reciprocally, if for every continuously differentiable function f the PAKKT point x^* is also KKT, then x^* satisfies the PAKKT-regular condition.*

Proof. If x^* is a PAKKT point, there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}_+^p$, $k \geq 1$, such that $x^k \rightarrow x^*$, (6) to (8) hold, and $\nabla f(x^k) + \omega^k \rightarrow 0$ where

$$\omega^k = \sum_{i=1}^m \lambda_i^k \nabla h_i(x^k) + \sum_{j=1}^p \mu_j^k \nabla g_j(x^k).$$

By (6) we can suppose without loss of generality that $\mu_j^k = 0$ whenever $j \notin I_g(x^*)$. As in the PAKKT definition, we consider $\delta_k = \|(1, \lambda^k, \mu^k)\|_\infty$. Let us define the sets $I_+ = \{i \in \{1, \dots, m\} \mid \lim_k |\lambda_i^k| / \delta_k > 0\}$ and $J_+ = \{j \in I_g(x^*) \mid \lim_k \mu_j^k / \delta_k > 0\}$, and for each k we take

$$\alpha_k = \min \left\{ 1/k, \min_{i \in I_+} \{\lambda_i^k h_i(x^k)\}, \min_{j \in J_+} \{\mu_j^k g_j(x^k)\} \right\}$$

and

$$\beta_k = \max \left\{ \frac{1}{k}, \max_{i \notin I_+} \frac{|\lambda_i^k|}{\delta_k}, \max_{j \notin J_+} \frac{\mu_j^k}{\delta_k} \right\} + \frac{1}{k}.$$

We note that $\alpha_k \downarrow 0$, $\beta_k \downarrow 0$ and $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$ for all k large enough. As x^* fulfills the PAKKT-regular condition, we have

$$-\nabla f(x^*) = \lim_k \omega^k \in \limsup_k K_+(x^k, \alpha_k, \beta_k) \subset \limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta) \subset K_+(x^*, 0, 0),$$

that is, x^* is a KKT point. This proves the first statement.

Now let us show the reciprocal. Let $w^* \in \limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta)$. Then there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\omega^k\} \subset \mathbb{R}^n$, $\{\alpha_k\} \subset \mathbb{R}$ and $\{\beta_k\} \subset \mathbb{R}$ such that $x^k \rightarrow x^*$, $\omega^k \rightarrow \omega^*$, $\alpha_k \downarrow 0$, $\beta_k \downarrow 0$ and $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$ for all k . Furthermore, for each k there are $\lambda^k \in \mathbb{R}^m$ and $\mu^k \in \mathbb{R}_+^{|I_g(x^*)|}$ such that

$$\omega^k = \sum_{i=1}^m \lambda_i^k \nabla h_i(x^k) + \sum_{j \in I_g(x^*)} \mu_j^k \nabla g_j(x^k). \quad (10)$$

We define $f(x) = -(\omega^*)^t x$. If $\lim_k |\lambda_i^k|/\delta_k > 0$ then $|\lambda_i^k| > \beta_k \delta_k$ for all k sufficiently large (the same happens with μ). In other words, the control over the sign of the multipliers performed by (7) and (8) is encapsulated in the expression $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$. Therefore, as $\nabla f(x^k) + \omega^k = -\omega^* + \omega^k \rightarrow 0$, we conclude that x^* is a PAKKT point. By hypothesis, x^* is a KKT point, and hence $\lim_k \omega^k = -\nabla f(x^*) \in K_+(x^*, 0, 0)$. This concludes the proof. \square

As a consequence of Theorems 2.1 and 2.2, it follows that any minimizer of (P) satisfying the PAKKT-regular condition is a KKT point. Equivalently, we obtain the next result.

Corollary 2.1. *PAKKT-regular is a constraint qualification.*

As expected, every KKT point is a PAKKT point (Lemma 2.1 below). However, an observation must be taken into account: consider, for example, the two constraints $g_1(x) = x \leq 0$, $g_2(x) = -x \leq 0$, and the constant objective function $f(x) = 1$. The origin is a KKT point with multipliers $\mu_1 = \mu_2 = 1$. In this case, any point $x \neq 0$ near the origin satisfies $\mu_1 g_1(x) < 0$ or $\mu_2 g_2(x) < 0$. In other words, this situation is not suitable for the PAKKT condition. But note that the Lagrange multipliers are not unique in this example. Fortunately, a KKT point always admits Lagrange multipliers with adequate signs for the PAKKT condition.

Lemma 2.1. *Every KKT point is a PAKKT point.*

Proof. Let x^* be a KKT point with associated multipliers λ and μ . We will show that there is a PAKKT sequence associated with x^* . In fact, let us consider the sets I and J of indexes of nonzero multipliers λ_i and μ_j , respectively. If $I = J = \emptyset$ then a PAKKT sequence is simply $x^k = x^*$ with $\lambda^k = 0$ and $\mu^k = 0$, for all k . We then suppose that at least one of the sets I and J are nonempty. By [4, Lemma 1] there are sets $\mathcal{I} \subset I$ and $\mathcal{J} \subset J$, and vectors $\hat{\lambda}_{\mathcal{I}}, \hat{\mu}_{\mathcal{J}}$ such that

$$\nabla f(x^*) + \sum_{i \in \mathcal{I}} \hat{\lambda}_i \nabla h_i(x^*) + \sum_{j \in \mathcal{J}} \hat{\mu}_j \nabla g_j(x^*) = 0,$$

$\hat{\lambda}_i \neq 0$ for all $i \in \mathcal{I}$, $\hat{\mu}_j > 0$ for all $j \in \mathcal{J}$, and the set of corresponding gradients

$$\{\nabla h_i(x^*), \nabla g_j(x^*) \mid i \in \mathcal{I}, j \in \mathcal{J}\}$$

is linearly independent (we implicitly consider only the nontrivial case $\mathcal{I} \cup \mathcal{J} \neq \emptyset$). In particular, taking $\hat{\lambda}_i = 0$, $i \notin \mathcal{I}$, and $\hat{\mu}_j = 0$, $j \notin \mathcal{J}$, the vectors $\hat{\lambda}$ and $\hat{\mu}$ are KKT multipliers for x^* . We then define the constant sequences

$$\lambda^k = \hat{\lambda} \quad \text{and} \quad \mu^k = \hat{\mu}$$

for all k . Note that the only multipliers that are taken into account in the expressions (7) and (8) are those with indexes in \mathcal{I} and \mathcal{J} .

Now, we will show that there exists a (PAKKT) sequence $\{x^k\}$, converging to x^* , such that (7) and (8) are satisfied with $\{\lambda^k = \hat{\lambda}\}$ and $\{\mu^k = \hat{\mu}\}$. To do this, we consider for $\gamma > 0$, $i \in \mathcal{I}$ and $j \in \mathcal{J}$ the sets

$$\mathcal{H}_i^\gamma = \left\{ y \in \mathbb{R}^n \setminus \{x^*\} \left| \begin{array}{l} \nabla h_i(x^*)^t \frac{y - x^*}{\|y - x^*\|_2} \geq \gamma \quad \text{if } \hat{\lambda}_i > 0 \\ \nabla h_i(x^*)^t \frac{y - x^*}{\|y - x^*\|_2} \leq -\gamma \quad \text{if } \hat{\lambda}_i < 0 \end{array} \right. \right\}$$

and

$$\mathcal{G}_j^\gamma = \left\{ y \in \mathbb{R}^n \setminus \{x^*\} \left| \nabla g_j(x^*)^t \frac{y - x^*}{\|y - x^*\|_2} \geq \gamma \right. \right\}.$$

Note that these sets are nonempty for all $\gamma > 0$ small enough, since $\nabla g_j(x^*) + x^* \in \mathcal{G}_j^\gamma$ for all $0 < \gamma \leq \|\nabla g_j(x^*)\|_2$ (analogously for \mathcal{H}_i^γ). We affirm that for each $j \in \mathcal{J}$ and $\gamma > 0$ there is an open ball $\mathcal{B}_j(x^*)$ with radius $\omega_j(\gamma) > 0$, centered at x^* , such that

$$g_j(y) > 0, \quad \forall y \in \mathcal{G}_j^\gamma \cap \mathcal{B}_j(x^*). \quad (11)$$

In fact, by the smoothness of function g_j , we can write

$$g_j(y) = g_j(x^*) + \nabla g_j(x^*)^t(y - x^*) + r_j(y - x^*)$$

where $r_j(y - x^*)/\|y - x^*\|_2 \rightarrow 0$ when $y \rightarrow x^*$. As $j \in \mathcal{J} \subset I_g(x^*)$, it follows that

$$\frac{g_j(y)}{\|y - x^*\|_2} = \nabla g_j(x^*)^t \frac{y - x^*}{\|y - x^*\|_2} + \frac{r_j(y - x^*)}{\|y - x^*\|_2} \geq \frac{\gamma}{2} > 0$$

for all $y \in \mathcal{G}_j$ close to x^* . Analogously, for each $i \in \mathcal{I}$ and $\gamma > 0$, there is an open ball $\mathcal{B}_i(x^*)$ with radius $\omega_i(\gamma) > 0$, centered at x^* , such that

$$h_i(y) \begin{cases} > 0 & \text{if } \hat{\lambda}_i > 0 \\ < 0 & \text{if } \hat{\lambda}_i < 0 \end{cases}, \quad \forall y \in \mathcal{H}_i^\gamma \cap \mathcal{B}_i(x^*). \quad (12)$$

Finally, it is sufficient to show that for some $\gamma > 0$, the intersection

$$\left(\bigcap_{i \in \mathcal{I}} \mathcal{H}_i^\gamma \right) \cap \left(\bigcap_{j \in \mathcal{J}} \mathcal{G}_j^\gamma \right) \quad (13)$$

contains points arbitrarily close to x^* , since in this case any sequence $\{x^k\}$ in this intersection converging to x^* will be a PAKKT sequence associated with the constant sequences $\{\lambda^k = \hat{\lambda}\}$ and $\{\mu^k = \hat{\mu}\}$, by (11) and (12) (or taking a subsequence of $\{x^k\}$ with k large enough if necessary). See Figure 1. Let us consider the set

$$X' = \{x \mid h_i(x) \geq 0, h_l(x) \leq 0, g_j(x) \geq 0, \quad i \in \mathcal{I}_+, l \in \mathcal{I}_-, j \in \mathcal{J}\},$$

where $\mathcal{I}_+ = \{i \in \mathcal{I} \mid \hat{\lambda}_i > 0\}$ and $\mathcal{I}_- = \{i \in \mathcal{I} \mid \hat{\lambda}_i < 0\}$. With respect to X' , the linear independence constraint qualification holds at x^* and therefore the Mangasarian-Fromovitz CQ also holds at x^* . Thus, there is an unitary d such that

$$\nabla h_i(x^*)^t d > 0, \quad \nabla h_l(x^*)^t d < 0, \quad \nabla g_j(x^*)^t d > 0, \quad i \in \mathcal{I}_+, l \in \mathcal{I}_-, j \in \mathcal{J}.$$

Taking

$$\gamma = \min \{ \nabla h_i(x^*)^t d, -\nabla h_l(x^*)^t d, \nabla g_j(x^*)^t d \mid i \in \mathcal{I}_+, l \in \mathcal{I}_-, j \in \mathcal{J} \} > 0$$

and $y \in \mathbb{R}^n$ such that $d = (y - x^*)/\|y - x^*\|_2$, we conclude that this y belongs to the intersection (13). Since such a y can be taken arbitrarily close to x^* , the proof is complete. \square

Figure 1: Geometry for Lemma 2.1. The constraint $g_3(x) \leq 0$ is redundant, and the gradients of the other active constraints at x^* are linearly independent. The sequence $\{x^k\}$ belongs to the set $\mathcal{G}_1^\gamma \cap \mathcal{G}_2^\gamma$, and converges to x^* from the outside of the feasible set.

3 Relations

3.1 Relations with other sequential optimality conditions

In this subsection, we establish the relations between PAKKT condition and other sequential optimality conditions in the literature. In addition to the AKKT condition presented in the introduction, we consider the following ones:

- We say that $x^* \in X$ is a *Complementary Approximate KKT* (CAKKT) [7] point if there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}_+^p$ such that (4), (5) hold and, for all $i = 1, \dots, m$ and $j = 1, \dots, p$,

$$\lim_k \lambda_i^k h_i(x^k) = 0 \quad \text{and} \quad \lim_k \mu_j^k g_j(x^k) = 0.$$

In this case, $\{x^k\}$ is called a *CAKKT sequence*.

- For each $x \in \mathbb{R}^n$, let us consider the linear approximation of the feasible set X of (P) at x

$$\Omega(x) = \left\{ z \in \mathbb{R}^n \left| \begin{array}{ll} g_j(x) + \nabla g_j(x)^t(z-x) \leq 0 & \text{if } g_j(x) < 0 \\ \nabla g_j(x)^t(z-x) \leq 0 & \text{if } g_j(x) \geq 0 \\ \nabla h(x)^t(z-x) = 0 & \end{array} \right. \right\}.$$

We define the *approximate gradient projection* by $d(x) = P_{\Omega(x)}(x - \nabla f(x)) - x$, where $P_C(\cdot)$ denotes the orthogonal projection onto the closed and convex set C . We say that $x^* \in X$ is an *Approximate Gradient Projection* (AGP) [25] point if there is a sequence $\{x^k\} \subset \mathbb{R}^n$ converging to x^* such that $d(x^k) \rightarrow 0$.

Both of the above conditions have been proved to be sequential optimality conditions [7, 25]. Also, it is known that CAKKT is strictly stronger than AGP [7], which in turn is strictly stronger than AKKT [3]. CAKKT sequences are generated by the augmented Lagrangian method of the next section with an additional hypothesis that the sum-of-squares infeasibility measure satisfies a generalized Lojasiewicz inequality (see [7] for details). On the other hand, AGP sequences are useful to analyze accumulation points of inexact restoration techniques [26].

Since AKKT condition is exactly PAKKT without expressions (7) and (8), the next result is trivial.

Theorem 3.1. *Every PAKKT sequence is also an AKKT sequence. In particular, every PAKKT point is an AKKT point.*

Example 3.1 (a CAKKT point may not be PAKKT). *Let us consider the problem*

$$\min_x \frac{(x_1 - 1)^2}{2} + \frac{(x_2 + 1)^2}{2} \quad \text{subject to} \quad x_1 x_2 \leq 0,$$

for which

$$\nabla_x L(x, \mu) = \begin{bmatrix} x_1 - 1 \\ x_2 + 1 \end{bmatrix} + \mu \begin{bmatrix} x_2 \\ x_1 \end{bmatrix}.$$

The origin is a CAKKT point with the sequences defined by $x^k = (-1/k, 1/k)$ and $\mu^k = k$ for all $k \geq 1$. Furthermore, any CAKKT sequence $\{x^k\}$ converging to the origin with associated $\{\mu^k\}$ satisfies $\lim_k \mu^k x_1^k = -1$ and $\lim_k \mu^k x_2^k = 1$. Thus, for all k sufficiently large we have $\text{sgn } \mu^k = 1$, $\text{sgn } x_1^k = -1$ and $\text{sgn } x_2^k = 1$, and hence $\text{sgn}(\mu^k x_1^k x_2^k) = -1$. That is, the origin is not a PAKKT point.

Example 3.2 (a PAKKT point may not be AGP). *Let us consider the problem*

$$\min_x x_2 \quad \text{subject to} \quad x_1^2 x_2 = 0, \quad -x_1 \leq 0.$$

The point $(0, -1)$ is PAKKT with the sequences defined by $x^k = (1/k, -1)$, $\lambda^k = -k^2$ and $\mu^k = 2k$ for all $k \geq 1$. By straightforward calculations we obtain

$$\Omega(x_1, x_2) = \left\{ (z_1, z_2) \in \mathbb{R}^2 \left| \begin{array}{l} z_1 \geq \min\{0, x_1\} \\ (2x_1 x_2)z_1 + (x_1^2)z_2 = 3x_1^2 x_2 \end{array} \right. \right\}.$$

Thus, given a sequence $\{x^k\}$ converging to $(0, -1)$, the set $\Omega(x^k)$ tends to a vertical semi-line within the y -axis if $x_1^k \neq 0$ or it is the semi-plane $z_1 \geq 0$ otherwise. As $x^k - \nabla f(x^k) = (x_1^k, x_2^k - 1) \rightarrow (0, -2)$, we always have $\|d(x^k)\|_\infty = \|P_{\Omega(x^k)}(x^k - \nabla f(x^k)) - x^k\|_\infty \rightarrow 1$. Then $(0, -1)$ is not an AGP point.

In particular, as every CAKKT point is AGP (and thus AKKT), Example 3.1 also shows that exist AGP and AKKT points that are not PAKKT points. In the same way, Example 3.2 implies that exist PAKKT points that are not CAKKT. Figure 2 summarizes the relationship between all sequential optimality conditions discussed here.

Figure 2: Relations of PAKKT and other sequential optimality conditions. An arrow between two sequential conditions means that one is strictly stronger than the other. Note that PAKKT is independent of AGP and CAKKT conditions.

3.2 Relations between PAKKT-regular and other known CQs

In the section 2, we demonstrated that PAKKT-regular is a constraint qualification (Corollary 2.1). Now we discuss the relationship between PAKKT-regular and other CQs in the literature, giving an updated landscape of various CQs.

We already mentioned that the weakest strict constraint qualification for the AKKT sequential optimality condition is the AKKT-regular CQ (also called cone continuity property – CCP) [8]. Defining the cone

$$K_+(x, 0, \infty) = \left\{ \sum_{i=1}^m \lambda_i \nabla h_i(x) + \sum_{j \in I_g(x^*)} \mu_j g_j(x) \mid \lambda \in \mathbb{R}^m, \mu_j \in \mathbb{R}_+, j \in I_g(x^*) \right\},$$

we say that $x^* \in X$ satisfies the AKKT-regular condition if the multifunction $x \in \mathbb{R}^n \rightrightarrows K_+(x, 0, \infty)$ is outer semicontinuous at x^* , that is, if

$$\limsup_{x \rightarrow x^*} K_+(x, 0, \infty) \subset K_+(x^*, 0, \infty).$$

Note that $K_+(x, \alpha, \beta) \subset K_+(x, 0, \infty)$ for all $x \in \mathbb{R}^n$ and $\alpha, \beta > 0$. Furthermore $K_+(x, 0, \infty) = K_+(x, 0, 0)$ whenever x is feasible for (P). These observations are the key to prove the next result.

Theorem 3.2. *AKKT-regular implies PAKKT-regular.*

Proof. If x^* satisfies the AKKT-regular condition then

$$\limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta) \subset \limsup_{x \rightarrow x^*} K_+(x, 0, \infty) \subset K_+(x^*, 0, \infty) = K_+(x^*, 0, 0),$$

completing the proof. □

A natural constraint qualification associated with EFJ points is quasinormality (see for example [12]). Since PAKKT is an optimality condition that translates the sign control in the EFJ points to the sequential world, it is reasonable that PAKKT-regular and quasinormality CQs are connected. In the next, we discuss this relation.

Definition 3.1 ([22]). *We say that $x^* \in X$ satisfies the quasinormality constraint qualification if there are no $\lambda \in \mathbb{R}^m$ and $\mu \in \mathbb{R}_+^{|I_g(x^*)|}$ such that*

$$1. \sum_{i=1}^m \lambda_i \nabla h_i(x^*) + \sum_{j \in I_g(x^*)} \mu_j \nabla g_j(x^*) = 0;$$

2. $(\lambda, \mu) \neq 0$; and

3. in every neighborhood $\mathcal{B}(x^*)$ of x^* there is a $x \in \mathcal{B}(x^*)$ such that $\lambda_i h_i(x) > 0$ for all i with $\lambda_i \neq 0$ and $\mu_j g_j(x) > 0$ for all j with $\mu_j > 0$.

Theorem 3.3. *Quasinormality implies PAKKT-regular.*

Proof. We suppose that x^* is not PAKKT-regular. Then exists

$$\omega^* \in \left(\limsup_{x \rightarrow x^*, \alpha \downarrow 0, \beta \downarrow 0} K_+(x, \alpha, \beta) \right) \setminus K_+(x^*, 0, 0).$$

Let us take $\{x^k\} \subset \mathbb{R}^n$, $\{\omega^k\} \subset \mathbb{R}^n$, $\{\alpha_k\} \subset \mathbb{R}$ and $\{\beta_k\} \subset \mathbb{R}$ such that $x^k \rightarrow x^*$, $\omega^k \rightarrow \omega^*$, $\alpha_k \downarrow 0$, $\beta_k \downarrow 0$ and $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$ for all $k \geq 1$, where ω^k is as in (10). We define $\tilde{\delta}_k = \|(\lambda^k, \mu^k)\|_\infty$. The sequence $\{\tilde{\delta}_k\}$ is unbounded because, otherwise, we would have $\omega^* \in K_+(x^*, 0, 0)$ since $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$ for all k . Thus dividing (10) by $\tilde{\delta}_k$ and taking the limit we obtain

$$\sum_{i=1}^m \lambda_i^* \nabla h_i(x^*) + \sum_{j \in I_g(x^*)} \mu_j^* \nabla g_j(x^*) = 0$$

where $(\lambda^*, \mu^*) \neq 0$. Given a neighborhood $\mathcal{B}(x^*)$ of x^* , we have for some k large enough $x^k \in \mathcal{B}(x^*)$ and $\text{sgn}(\lambda_i^* h_i(x^k)) = \text{sgn}(\lambda_i^k h_i(x^k)) = 1$ whenever $\lambda_i^* \neq 0$ (note that $\lim_k \lambda_i^k / \tilde{\delta}_k = \lambda_i^* \neq 0$ implies $|\lambda_i^k| > \beta_k \tilde{\delta}_k = \beta_k \|(\lambda^k, \mu^k)\|_\infty$ for all k sufficiently large). The same happens with μ^* . Hence x^* does not satisfy the quasinormality CQ, which completes the proof. \square

As we already mentioned, AKKT-regular and quasinormality are independent constraint qualifications [8]. Then, from Theorems 3.2 and 3.3 we conclude that PAKKT-regular does not imply any of these two conditions. A geometric comparison between AKKT-regular and PAKKT-regular CQs is given in Figure 3.

In order to provide a complete relationship between PAKKT-regular and other known constraint qualifications, we will now prove that PAKKT-regular is stronger than Abadie's CQ [1]. We denote the tangent cone to the feasible set X of (P) at x^* by $\mathcal{T}(x^*)$, and its linearization by $\mathcal{L}(x^*)$. Furthermore, C° will denote the polar of the set C . Recall that Abadie's CQ consists of the equality $\mathcal{T}(x^*) = \mathcal{L}(x^*)$.

Lemma 3.1 ([8, Lemma 4.3]). *For each $x^* \in X$ and $\omega^* \in \mathcal{T}^\circ(x^*)$, there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}_+^p$ such that $x^k \rightarrow x^*$,*

1. $\omega^k = \sum_{i=1}^m \lambda_i^k \nabla h_i(x^k) + \sum_{j=1}^p \mu_j^k \nabla g_j(x^k)$ converges to ω^* ,
2. $\lambda^k = kh(x^k)$ and $\mu^k = kg(x^k)_+$.

Theorem 3.4. *PAKKT-regular implies Abadie's CQ.*

Proof. The multipliers in the item (2.) of Lemma 3.1 have the same sign of their corresponding constraints for all k . Thus the proof follows the same arguments used in [8, Theorem 4.4], taking appropriate sequences $\{\alpha_k\}$ and $\{\beta_k\}$. \square

Example 3.3 (Abadie's CQ does not imply PAKKT-regular). *Let us consider the constraints*

$$\begin{aligned} g_1(x) &= x_2 - x_1^2, & g_2(x) &= -x_2 - x_1^2, & g_3(x) &= x_2 - x_1^5, \\ g_4(x) &= -x_2 - x_1^5 & \text{and} & & g_5(x) &= -x_1. \end{aligned}$$

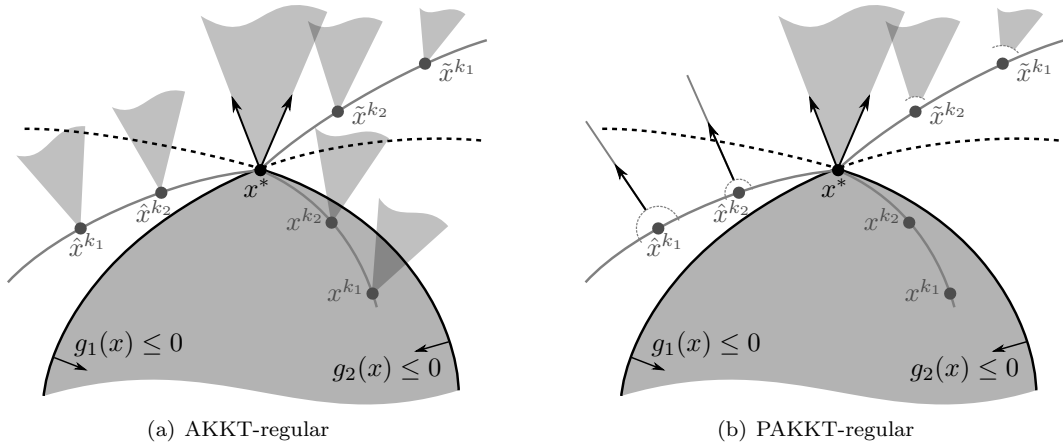

Figure 3: Geometric interpretation of AKKT-regular and PAKKT-regular conditions. The inequality constraints $g_1(x) \leq 0$ and $g_2(x) \leq 0$ are active at x^* . The sequence $\{x^k\}$ is feasible with respect to the two constraints, $\{\hat{x}^k\}$ is feasible only with respect to the second one and $\{\tilde{x}^k\}$ is infeasible with respect to both constraints. In the cones $K_+(\cdot, 0, \infty)$ of AKKT-regular there are no restrictions on the sign of the multipliers beyond non-negativity, and at all points of the sequences, both gradients ∇g_1 and ∇g_2 take place (figure (a)). The sets $K_+(\cdot, \alpha, \beta)$ are possibly “discontiguous” in the following sense: if $0 \neq z \in K_+(x, \alpha, \beta)$ then it is possible that $\gamma z \notin K_+(x, \alpha, \beta)$ for all $\gamma \in [a, b]$ whenever α is not sufficiently large, where a and b depend on α and β . Figure (b) illustrates the case where $\beta = 0$. In this situation, the multipliers related to strict satisfied constraints vanish due to the sign control in the PAKKT-regular condition: for the sequence $\{x^k\}$, both multipliers are null and then $K_+(\cdot, \alpha, 0) = \{0\}$; for $\{\hat{x}^k\}$ only ∇g_1 can be present; and for $\{\tilde{x}^k\}$ both gradients may compose the set $K_+(\cdot, \alpha, 0)$.

All these constraints are active at the point $x^* = (0, 0)$, which fulfills the Abadie’s CQ since $\mathcal{T}(x^*) = \mathcal{L}(x^*) = \{(x_1, 0) \mid x_1 \in \mathbb{R}_+\}$. We affirm that PAKKT-regular does not hold at x^* . In fact, consider the vector $\omega^* = (1, 0)$. With the sequences defined by $x^k = (-1/k, 0)$, $\mu^k = (k/4, k/4, k^3, k^3, 0)$, $\alpha_k = 1/k^2$ and $\beta_k = 1/k$ for all $k \geq 1$ we have $\alpha_k \downarrow 0$, $\beta_k \downarrow 0$, $\delta_k = \|(1, \mu^k)\|_\infty = k^3$,

$$\omega^k = \sum_{j=1}^5 \mu_j^k \nabla g_j(x^k) = \begin{bmatrix} 1/2 \\ k/4 \end{bmatrix} + \begin{bmatrix} 1/2 \\ -k/4 \end{bmatrix} + \begin{bmatrix} -5/k \\ k^3 \end{bmatrix} + \begin{bmatrix} -5/k \\ -k^3 \end{bmatrix} \rightarrow \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \omega^*$$

and, for all k , $\mu_1^k = \mu_2^k = k/4 < k^2 = \beta_k \delta_k$, $\mu_5^k = 0 < \beta_k \delta_k$ and $\mu_3^k = \mu_4^k = k^3 > \beta_k \delta_k$ with $\mu_3^k g_3(x^k) = \mu_4^k g_4(x^k) = 1/k^2 \geq \alpha_k$. Therefore $\omega^k \in K_+(x^k, \alpha_k, \beta_k)$ for all k , but $\omega^* \notin K_+(x^*, 0, 0) = \{(-x_1, x_2) \mid x_1 \in \mathbb{R}_+, x_2 \in \mathbb{R}\}$. That is, the origin does not satisfy the PAKKT-regular CQ.

Figure 4 shows the relations between CQs. We emphasize that PAKKT-regular unifies the branches from the independent CQs AKKT-regular and quasinormality under the augmented Lagrangian convergence theory, as we will see in the next section.

4 Global convergence of the augmented Lagrangian method using the PAKKT-regular constraint qualification

Next we present the augmented Lagrangian algorithm proposed to solve (P) [15].

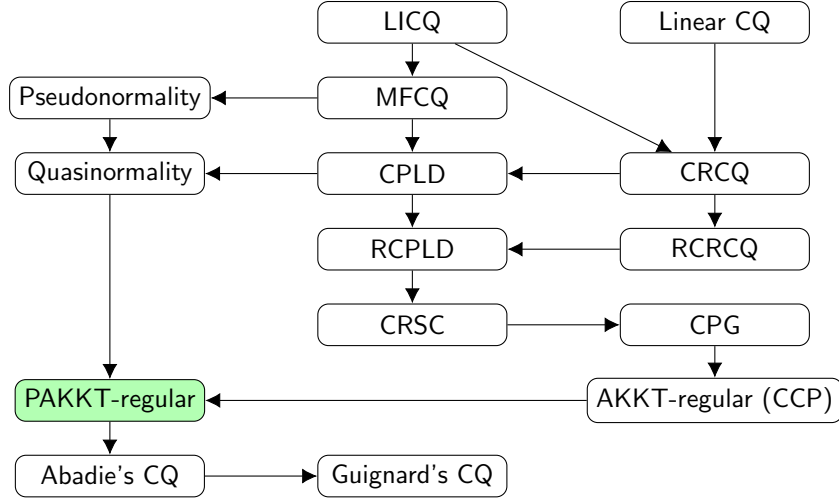

Figure 4: Updated landscape of constraint qualifications. The arrows indicate logical implications. Note that the independent CQs AKKT-regular and quasinormality imply PAKKT-regular, which in turn is strictly stronger than Abadie's CQ.

Algorithm 1 Augmented Lagrangian method

Let $x^1 \in \mathbb{R}^n$ be an arbitrary initial point. The given parameters for the execution of the algorithm are: $\tau \in [0, 1)$, $\gamma > 1$, $\lambda_{\min} < \lambda_{\max}$, $\mu_{\max} > 0$ and $\rho_1 > 0$. Also, let $\bar{\lambda}^1 \in [\lambda_{\min}, \lambda_{\max}]^m$ and $\bar{\mu}^1 \in [0, \mu_{\max}]^p$ be the initial Lagrange multipliers estimates. Finally, $\{\varepsilon_k\} \subset \mathbb{R}_+$ is a sequence of tolerance parameters such that $\lim_k \varepsilon_k = 0$. Initialize $k \leftarrow 1$.

Step 1. (Solving the subproblem) Compute (if possible) $x^k \in \mathbb{R}^n$ such that

$$\|\nabla_x L_{\rho_k}(x^k, \bar{\lambda}^k, \bar{\mu}^k)\| \leq \varepsilon_k. \quad (14)$$

If it is not possible, stop the execution of the algorithm declaring failure.

Step 2. (Estimate new multipliers) Compute

$$\lambda^k = \bar{\lambda}^k + \rho_k h(x^k) \quad \text{and} \quad \mu^k = (\bar{\mu}^k + \rho_k g(x^k))_+.$$

Step 3. (Update the penalty parameter) Define

$$V^k = \frac{\mu^k - \bar{\mu}^k}{\rho_k}. \quad (15)$$

If $k = 1$ or

$$\max \{\|h(x^k)\|, \|V^k\|\} \leq \tau \max \{\|h(x^{k-1})\|, \|V^{k-1}\|\},$$

choose $\rho_{k+1} = \rho_k$. Otherwise, define $\rho_{k+1} = \gamma \rho_k$.

Step 4. (Update multipliers estimates) Compute $\bar{\lambda}^{k+1} \in [\lambda_{\min}, \lambda_{\max}]^m$ and $\bar{\mu}^{k+1} \in [0, \mu_{\max}]^p$.

Step 5. (Begin a new iteration) Set $k \leftarrow k + 1$ and go to step 1.

The vector V^k is responsible for measuring infeasibility and non-complementarity with respect to the

inequality constraints. If the PHR augmented Lagrangian (1) is used then

$$V^k = \max \left\{ g(x^k), -\frac{\bar{\mu}^k}{\rho_k} \right\}, \quad (16)$$

according to [15]. In this paper, we only deal with the augmented Lagrangian (1) (and then we always have (16)), but we note that the general form (15) is also appropriate for the case when a non-quadratic penalty augmented Lagrangian function is employed, as in [18, 29].

It is known that when Algorithm 1 does not stop by failure, it generates an AKKT sequence for the problem (P) if its limit point is feasible (see [15]). In particular, every feasible accumulation point of this algorithm is an AKKT point. Next we prove that it also reaches the stronger PAKKT points (from now on, we suppose that the method generates an infinite primal sequence).

Theorem 4.1. *Every feasible accumulation point $x^* \in X$ generated by Algorithm 1 is a PAKKT point.*

Proof. Let $\{x^k\}$, $\{\bar{\lambda}^k\}$, $\{\bar{\mu}^k\}$ and $\{\rho_k\}$ be sequences generated by Algorithm 1 and x^* a feasible accumulation point of $\{x^k\}$, let us say, $\lim_{k \in K} x^k = x^*$. By (14) we have

$$\lim_{k \in K} \nabla_x L(x^k, \lambda^k, \mu^k) = \lim_{k \in K} [\nabla f(x^k) + \nabla h(x^k) \lambda^k + \nabla g(x^k) \mu^k] = 0, \quad (17)$$

where

$$\lambda^k = \bar{\lambda}^k + \rho_k h(x^k) \quad \text{and} \quad \mu^k = (\bar{\mu}^k + \rho_k g(x^k))_+. \quad (18)$$

With the sequence $\{(x^k, \lambda^k, \mu^k)\}$, (17) implies (5). If $\rho_k \rightarrow \infty$ then $\mu_j^k = 0$ whenever $g_j(x^*) < 0$ and k is sufficiently large. If $\{\rho_k\}$ is bounded then $\lim_k V^k = 0$, and thus $\lim_k \mu_j^k = 0$ whenever $g_j(x^*) < 0$. Therefore $\lim_k \mu_j^k = 0$, and (6) holds.

Let us define $\delta_k = \|(1, \lambda^k, \mu^k)\|_\infty$ as in the PAKKT definition. If $\{\delta_k\}_{k \in K}$ is unbounded, then there is an infinite index set $K' \subset K$ such that $\{\delta_k\}_{k \in K'}$ remains unbounded, $\lim_{k \in K'} \lambda_i^k / \delta_k$ exists for all i and $\lim_{k \in K'} \mu_j^k / \delta_k$ exists for all j . From the boundedness of $\{\bar{\lambda}^k\}$ we have that, for each i such that $\lim_{k \in K'} \lambda_i^k / \delta_k \neq 0$,

$$0 \neq \lim_{k \in K'} \left[\frac{\bar{\lambda}_i^k}{\delta_k} + \frac{\rho_k h_i(x^k)}{\delta_k} \right] = \lim_{k \in K'} \frac{\rho_k h_i(x^k)}{\delta_k} \Rightarrow \lambda_i^k h_i(x^k) > 0, \quad \forall k \geq k_i, k \in K',$$

for some $k_i \geq 1$. Then (7) is satisfied on a subsequence of $\{(x^k, \lambda^k, \mu^k)\}_{k \in K'}$ initializing from an index greater than $\max_i k_i$. The condition (8) is obtained in the same way for the indexes j such that $g_j(x^*) = 0$. Now, if $g_j(x^*) < 0$ then (6) implies $\lim_{k \in K'} \mu_j^k / \delta_k \leq \lim_{k \in K'} \mu_j^k = 0$, and these indexes j do not violate (8). Therefore, we showed that $\{x^k\}_{k \in K'}$ is a PAKKT sequence, and thus x^* is a PAKKT point when $\{\delta_k\}_{k \in K}$ is unbounded.

If $\{\delta_k\}_{k \in K}$ is bounded then, taking the limit (17) on an appropriate subsequence, we conclude that x^* is KKT, and then a PAKKT point by Lemma 2.1 (not necessarily with the same primal-dual sequence generated by the method). \square

It is important to note that Algorithm 1 generates PAKKT points, but not necessarily PAKKT sequences. That is, we claim that for each feasible accumulation point x^* there is a correspondent PAKKT sequence, but not necessarily the generated sequence $\{x^k\}$ has a subsequence with this property. Specifically, when the dual sequence $\{\delta_k\}$ is unbounded, $\{x^k\}$ has a PAKKT subsequence associated with x^* . But in the proof of the above theorem we do not have any guarantee that a subsequence generated by the method is a PAKKT sequence if $\{\delta_k\}$ is bounded. Of course, it is not a trouble because in the last case the limit point is already a KKT point. The next example shows that this situation may occur.

Example 4.1. *Let us consider the minimization of $f(x) = x$ subject to $-x \leq 0$. Then $\nabla_x L_{\rho_k}(x_k, \mu_k) = 0$ iff $x_k = (\mu_k - 1)/\rho_k$. If we always choose $\bar{\mu}_{k+1} = 2$ in the step 4, we will have $(\bar{\mu}_k - \rho_k x_k)_+(-x_k) = -1/\rho_k < 0$ for all $k \geq 1$.*

Practical implementations of Algorithm 1 adopt the following updating rule for the Lagrange multipliers in the step 4:

$$\begin{aligned}\bar{\lambda}_i^{k+1} &= \min\{\lambda_{\max}, \max\{\lambda_{\min}, \bar{\lambda}_i^k + \rho_k h_i(x^k)\}\}, \quad i = 1, \dots, m, \\ \bar{\mu}_j^{k+1} &= \min\{\mu_{\max}, \max\{0, \bar{\mu}_j^k + \rho_k g_j(x^k)\}\}, \quad j = 1, \dots, p.\end{aligned}\tag{19}$$

This rule corresponds to projecting the estimates λ^k and μ^k from step 2 onto the boxes $[\lambda_{\min}, \lambda_{\max}]^m$ and $[0, \mu_{\max}]^p$, respectively. It is used, for example, in the implementation of the so-called augmented Lagrangian method ALGENCAN [2] provided by TANGO project (www.ime.usp.br/~egbirgin/tango). Even with this updating rule, there is no guarantee that a convergent subsequence generated by Algorithm 1 is a PAKKT sequence, as the next example illustrates.

Example 4.2. *Let us consider the same problem of Example 4.1*

$$\min_x x \quad \text{subject to} \quad -x \leq 0.$$

The origin is the global minimizer and it satisfies the well known linear independence constraint qualification. Although it is a KKT point (and then a PAKKT point by Lemma 2.1), Algorithm 1 may converge to the origin with a non-PAKKT primal sequence. In fact, consider the sequence defined by $x_k = 1/((k+1)^2 \rho_k)$, $k \geq 0$, which converges to the origin. We have $\nabla_x L_{\rho_k}(x_k, \bar{\mu}_k) = 1 - (\bar{\mu}_k - 1/(k+1)^2)_+ \rightarrow 0$ whenever $\bar{\mu}_k \rightarrow 1$. Fixed $\tau \in (0, 1)$, we also have $|V_{k-1}| = 1/(k^2 \rho_{k-1}) > \tau/((k+1)^2 \rho_k) = \tau|V_k|$ for all k large enough. If we initialize x_0 sufficiently closed to the origin, we can suppose without loss of generality that this occurs for all $k \geq 0$. Thus, as $x_k > 0$, we have $\bar{\mu}_{k+1} = \mu_{k+1} = (\bar{\mu}_k - \rho_k x_k)_+$ for all $k \geq 1$ and then

$$\bar{\mu}_{k+1} = \left[\bar{\mu}_k - \frac{1}{(k+1)^2} \right]_+ = \dots = \bar{\mu}_0 - \sum_{i=1}^{k+1} \frac{1}{i^2}.\tag{20}$$

The above series is convergent as $k \rightarrow \infty$, and hence it is possible to choose $\bar{\mu}_0 > 0$ so that $\lim_k \bar{\mu}_{k+1} = 1$ as we wanted. In this case $\bar{\mu}_k > 0$ for all k , and then the expression (20) makes sense. We also note that, as $\rho_{k+1} = \gamma \rho_k$ for all k , the iterate x_k only depends on ρ_0 and γ , avoiding cyclic definitions. This concludes the discussion.

In [21] the sequential complementarity (6) is changed by a more stringent condition, resulting in the so-called strong AKKT notion. We say that $x^* \in X$ is a *Strong AKKT* (SAKKT) point if there are sequences $\{x^k\} \subset \mathbb{R}^n$, $\{\lambda^k\} \subset \mathbb{R}^m$ and $\{\mu^k\} \subset \mathbb{R}_+^p$ such that (4), (5) hold and, for all k ,

$$g_j(x^k) < 0 \quad \Rightarrow \quad \mu_j^k = 0.\tag{21}$$

The authors of [21] also present some relations between SAKKT and AKKT, but no result linking SAKKT points to practical algorithms. The previous example shows, in particular, that Algorithm 1 can generate a non-SAKKT sequence. However, by [7, Theorem 4.1] and [21, Theorem 4.3], every CAKKT point is also SAKKT. Furthermore, when a very weak generalized Lojasiewicz inequality on the sum-of-squares infeasibility measure holds, Algorithm 1 generates CAKKT points [7] (the previous example satisfies this assumption). Thus, although Algorithm 1 does not always generate SAKKT-sequences, it reaches SAKKT points.

It was already known in the literature that the augmented Lagrangian method (Algorithm 1) converges to KKT points under the AKKT-regular constraint qualification [8]. Theorem 4.1 asserts that Algorithm 1 reaches PAKKT points, and then by Theorem 2.2 it converges to a KKT point under the less stringent CQ PAKKT-regular. The next result is a direct consequence of Theorems 2.2, 3.3 and 4.1. To the best of our knowledge, it is the first time it has been proved that a practical algorithm for general nonlinear constrained optimization converges to KKT points under the quasinormality CQ.

Corollary 4.1. *Let x^* be a feasible accumulation point of (P) generated by Algorithm 1. If x^* satisfies PAKKT-regular (and thus quasinormality) then x^* is a KKT point.*

4.1 Strength of the PAKKT condition: AKKT vs. PAKKT methods

As we have already mentioned in the introduction, sequential optimality conditions have been used to strengthen the theoretical convergence results of several methods. See [2, 3, 4, 7, 8, 9, 15, 25] and references therein. The goal is to prove that a specific method achieves, say, AKKT points. Thus, the theoretical convergence of this “AKKT method” is established under any constraint qualification that ensures that an AKKT point is actually KKT. In this sense, we improve the previous convergence results for the PHR augmented Lagrangian method by proving that it reaches PAKKT points (see Theorem 4.1 and Corollary 4.1).

The aim of this section is to illustrate how “PAKKT methods” may have significantly better theoretical convergence results than pure AKKT methods. For this purpose, we consider the the so-called *Mathematical Programs with Complementarity Constraints* (MPCC). It is worth noticing that, although we make some progress, we do not intend to extend existing convergence results for MPCC. In fact, it is known that this type of result was obtained for specific methods, in particular Algorithm 1 [10, 23]. On the other hand, our approach focus on the sequential optimality conditions, which do not depend on the method considered. We emphasize that the AKKT condition is naturally associated with stopping criteria adopted by practical algorithms, since it consists of a simple and computable inexact version of the KKT conditions (see (2)). Our theory ensures that methods based on external penalty approaches generate more than AKKT points, and then it helps to clarify why algorithms, such as Algorithm 1, have a good behaviour in MPCCs.

Firstly, we note that PAKKT methods are not worst than the AKKT methods, since every PAKKT point is an AKKT one (Theorem 3.1). Now, let us recall the MPCC (3) of the introduction:

$$\min_x (x_1 - 1)^2 + (x_2 - 1)^2 \quad \text{subject to} \quad x_1, x_2 \geq 0, \quad x_1 x_2 \leq 0. \quad (22)$$

We have shown that every feasible point of this problem is AKKT. This means that, at least in theory, a generic AKKT method can converge to an arbitrary feasible point. On the other hand, it is straightforward to verify that only the global solutions (1,0) and (0,1), and the point (0,0) are PAKKT. In other words, a generic PAKKT method has a drastically better theoretical convergence guarantee than the pure AKKT methods when applied to (22). This example shows that it is not possible to establish any reasonable convergence theory to the classical stationarity concepts for MPCC (S-, M-, C- or even W-stationarity) using the AKKT condition.

Let us analyze the previous problem in a more comprehensive way. The mathematical program with complementarity constraints can be generically stated as

$$\begin{aligned} & \min_x f(x) \\ & \text{subject to } h(x) = 0, \quad g(x) \leq 0, \\ & \quad H(x) \geq 0, \quad G(x) \geq 0, \quad H_i(x)G_i(x) \leq 0, \quad i = 1, \dots, s, \end{aligned} \quad (\text{MPCC})$$

where $f : \mathbb{R}^n \rightarrow \mathbb{R}$, $h : \mathbb{R}^n \rightarrow \mathbb{R}^m$, $g : \mathbb{R}^n \rightarrow \mathbb{R}^p$ and $H, G : \mathbb{R}^n \rightarrow \mathbb{R}^s$. We suppose that all these functions are continuously differentiable. The last s inequalities constraints, which ensures that G and H are complementary, are called *complementarity constraints*.

MPCCs constitute an important class of optimization problems, and there is an extensive literature about them (see for example [17] and references therein). They are highly degenerate problems. For instance, even with the simple constraints $x_1, x_2 \geq 0$ and $x_1 x_2 \leq 0$, it is straightforward to show the AKKT-regular CQ is not satisfied at any feasible point (in particular, even Abadie’s CQ fails at the origin). More generally we can expect, as in the problem (22), that every feasible point is AKKT in a wide variety of instances, since the complementary constraints of a generic MPCC can be rewritten in this simple form by inserting slack variables. On the other hand, when all the gradients of the active constraints, excluding the complementarity one, at a feasible point x^* are linearly independent (a condition known as MPCC-LICQ [30]) and when the *lower level strict complementarity* is satisfied at x^* , that is, when $G_i(x^*) > 0$ or $H_i(x^*) > 0$ for each $i = 1, \dots, s$, the quasinormality CQ holds. In fact, if

$(\lambda, \mu, \gamma^H, \gamma^G, \gamma^0) \in \mathbb{R}^m \times \mathbb{R}_+^p \times \mathbb{R}_+^{3s}$ is such that

$$\begin{aligned} \nabla h(x^*)\lambda + \nabla g(x^*)\mu - \nabla H(x^*)\gamma^H - \nabla G(x^*)\gamma^G \\ + \sum_{i=1}^s \gamma_i^0 (\nabla H_i(x^*)G_i(x^*) + \nabla G_i(x^*)H_i(x^*)) = 0 \end{aligned} \quad (23)$$

then, by the linear independence hypothesis, $\lambda = 0$, $\mu = 0$ and $\gamma_i^H - \gamma_i^0 G_i(x^*) = \gamma_i^G - \gamma_i^0 H_i(x^*) = 0$ for all $i = 1, \dots, s$. If $\gamma^0 = 0$ then $\gamma^H = \gamma^G = 0$, and thus quasinormality holds at x^* . If otherwise $\gamma_j^0 > 0$ for some fixed j then the lower level strict complementarity ensures that $\gamma_j^H = \gamma_j^0 G_j(x^*) > 0$ or $\gamma_j^G = \gamma_j^0 H_j(x^*) > 0$. We can suppose without loss of generality that $\gamma_j^H > 0$, and consequently $H_j(x^*) = 0$, $G_j(x^*) > 0$. By the continuity of G , we have $G_j(x) > 0$ for all x in a neighborhood $\mathcal{B}(x^*)$ of x^* . If $\gamma_j^H(-H_j(x)) = -\gamma_j^0 G_j(x^*)H_j(x) > 0$ then $H_j(x) < 0$ and $\gamma_j^0(H_j(x)G_j(x)) < 0$ for every $x \in \mathcal{B}(x^*)$. This contradicts the third condition of Definition 3.1, and thus x^* fulfills the quasinormality CQ (and consequently PAKKT-regular) as we want to prove. We conclude that, under the two hypotheses made on x^* , any PAKKT method converges to a KKT point x^* of (MPCC).

The same previous conclusion about the convergence of PAKKT methods in MPCCs can be obtained if we replace MPCC-LICQ by the much weaker condition MPCC-quasinormality defined in [24]. This condition is an adaptation of the quasinormality CQ to the MPCC setting. For a feasible x^* for (MPCC) we define the sets of indexes

$$I_H(x^*) = \{i \mid H_i(x^*) = 0\}, \quad I_G(x^*) = \{i \mid G_i(x^*) = 0\} \text{ and } I_0(x^*) = I_H(x^*) \cap I_G(x^*).$$

Note that $I_H(x^*) \cup I_G(x^*) = \{1, \dots, s\}$, and that the lower level strict complementarity at x^* consists of imposing $I_0(x^*) = \emptyset$.

Definition 4.1. *We say that a feasible point x^* conforms to MPCC-quasinormality CQ if there is no $(\lambda, \mu, \gamma^H, \gamma^G) \in \mathbb{R}^m \times \mathbb{R}_+^p \times \mathbb{R}^{2s}$ such that*

1. $\nabla h(x^*)\lambda + \nabla g(x^*)\mu - \nabla H(x^*)\gamma^H - \nabla G(x^*)\gamma^G = 0$;
2. $\mu_i = 0 \forall i \notin I_g(x^*)$, $\gamma_i^H = 0 \forall i \in I_G(x^*) \setminus I_H(x^*)$, $\gamma_i^G = 0 \forall i \in I_H(x^*) \setminus I_G(x^*)$ and either $\gamma_i^H > 0$, $\gamma_i^G > 0$ or $\gamma_i^H \gamma_i^G = 0 \forall i \in I_0(x^*)$;
3. $(\lambda, \mu, \gamma^H, \gamma^G) \neq 0$;
4. in every neighborhood $\mathcal{B}(x^*)$ of x^* there is a $x \in \mathcal{B}(x^*)$ such that

- $\lambda_i h_i(x) > 0$ for all i with $\lambda_i \neq 0$;
- $\mu_i g_i(x) > 0$ for all i with $\mu_i > 0$;
- $-\gamma_i^H H_i(x) > 0$ for all i with $\gamma_i^H \neq 0$; and
- $-\gamma_i^G G_i(x) > 0$ for all i with $\gamma_i^G \neq 0$.

Lemma 4.1. *Under lower level strict complementarity, MPCC-quasinormality implies the standard quasinormality CQ for (MPCC).*

Proof. Suppose that the standard quasinormality CQ is not satisfied at x^* . In other words, there are a nonzero vector $(\lambda, \mu, \gamma^H, \gamma^G, \gamma^0) \in \mathbb{R}^m \times \mathbb{R}_+^p \times \mathbb{R}_+^{3s}$ and a sequence $\{x^k\} \subset \mathbb{R}^n$ converging to x^* such that (23) holds,

$$\mu_i = 0 \forall i \notin I_g(x^*), \quad \gamma_i^H = 0 \forall i \notin I_H(x^*), \quad \gamma_i^G = 0 \forall i \notin I_G(x^*) \quad (24)$$

and, for all k ,

$$\lambda_i h_i(x^k) > 0 \text{ whenever } \lambda_i \neq 0; \quad (25a)$$

$$\mu_i g_i(x^k) > 0 \text{ whenever } \mu_i > 0; \quad (25b)$$

$$-\gamma_i^H H_i(x^k) > 0 \text{ whenever } \gamma_i^H > 0; \quad (25c)$$

$$-\gamma_i^G G_i(x^k) > 0 \text{ whenever } \gamma_i^G > 0; \text{ and} \quad (25d)$$

$$\gamma_i^0 H_i(x^k)G_i(x^k) > 0 \text{ whenever } \gamma_i^0 > 0. \quad (25e)$$

We note that, by the lower level strict complementarity assumption, $I_0(x^*) = \emptyset$, $i \notin I_H(x^*)$ iff $i \in I_G(x^*) = I_G(x^*) \setminus I_H(x^*)$ and $i \notin I_G(x^*)$ iff $i \in I_H(x^*) = I_H(x^*) \setminus I_G(x^*)$. That is, condition (2.) of definition 4.1 can be rewritten exactly as (24). Thus, if $\gamma_i^0 = 0$ for all $i = 1, \dots, s$ then the vector $(\lambda, \mu, \gamma^H, \gamma^G)$ and the sequence $\{x^k\}$ fulfill the four items of definition 4.1. In this case MPCC-quasinormality does not hold at x^* , and the statement is proved.

From now on, we suppose that $\gamma_j^0 > 0$ for a fixed index j . We can suppose without loss of generality that $j \in I_H(x^*)$, since the case $j \in I_G(x^*)$ is analogous. Equation (23) can be rewritten as

$$\nabla h(x^*)\lambda + \nabla g(x^*)\mu - \nabla H(x^*)\tilde{\gamma}^H - \nabla G(x^*)\tilde{\gamma}^G = 0$$

where, for all $i = 1, \dots, s$,

$$\tilde{\gamma}_i^H = \gamma_i^H - \gamma_i^0 G_i(x^*) \quad \text{and} \quad \tilde{\gamma}_i^G = \gamma_i^G - \gamma_i^0 H_i(x^*). \quad (26)$$

We affirm that $\tilde{\gamma}_j^H \neq 0$. In fact, suppose by contradiction that $\tilde{\gamma}_j^H = 0$. By the lower level strict complementarity at x^* , we have $j \notin I_G(x^*)$ and then

$$\gamma_j^0 G_j(x^k) > 0 \quad (27)$$

for all k sufficiently large, let us say, for all $k \in K$. By (26), we also have $\gamma_j^H = \gamma_j^0 G_j(x^*) > 0$. From condition (25c) we then obtain

$$H_j(x^k) < 0 \quad (28)$$

for all k . Therefore, from (27) and (28) we conclude that $\gamma_j^0 H_j(x^k) G_j(x^k) < 0$ for all $k \in K$, contradicting (25e). Thus $\tilde{\gamma}_j^H \neq 0$. In particular, the whole vector of multipliers $(\lambda, \mu, \tilde{\gamma}^H, \tilde{\gamma}^G)$ is nonzero.

Now, we note that (24) and the lower level strict complementarity imply $\tilde{\gamma}_i^H = 0 \forall i \notin I_H(x^*)$ and $\tilde{\gamma}_i^G = 0 \forall i \notin I_G(x^*)$. Furthermore, let us consider a nonzero multiplier $\tilde{\gamma}_i^H = \gamma_i^H - \gamma_i^0 G_i(x^*)$, $i \in I_H(x^*)$. If $\tilde{\gamma}_i^H > 0$ then necessarily $\gamma_i^H > 0$. By (25c), $H_i(x^k) < 0$ for all k and then $-\tilde{\gamma}_i^H H_i(x^k) > 0$ for all k . If otherwise $\tilde{\gamma}_i^H < 0$ then $\gamma_i^0 > 0$. Since $i \notin I_G(x^*)$, we have $G_i(x^k) > 0$ for all k large enough. Then, condition (25e) implies $H_i(x^k) > 0$ for these indexes k , and consequently $-\tilde{\gamma}_i^H H_i(x^k) > 0$ for all k large enough. Therefore, the nonzero vector $(\lambda, \mu, \tilde{\gamma}^H, \tilde{\gamma}^G)$ and the sequence $\{x^k\}$ (passing to a subsequence if necessary) violate the MPCC-quasinormality condition. This concludes the proof. \square

Theorem 4.2. *Let x^* be a feasible accumulation point of (MPCC) generated by a generic PAKKT method (in particular, Algorithm 1). Suppose that x^* satisfies MPCC-quasinormality and the lower level strict complementarity. Then x^* is a KKT point of (MPCC).*

Proof. This is a direct consequence of Lemma 4.1, and Theorems 2.2 and 3.3. \square

Theorem 4.2 extends Theorem 3.2 of [23] (see also [10]) in the case where the lower level strict complementarity holds. This previous result deals exclusively with augmented Lagrangian methods and was obtained assuming MPCC-LICQ, a much more stringent condition than MPCC-quasinormality. On the contrary, in addition to allowing us change MPCC-LICQ to the less stringent constraint qualification MPCC-quasinormality, the PAKKT condition able us to prove a result not exclusively valid for Algorithm 1, but for any PAKKT method.

When we deal with a ‘‘linear MPCC’’, i.e., a MPCC where all the functions h , g , H and G are affine, MPCC-quasinormality is always satisfied (see for instance [19]). In particular, Theorem 4.2 can be applied to this important class of problems.

Corollary 4.2. *Suppose that h , g , H and G are affine functions. If x^* is a feasible accumulation point of (MPCC) generated by a generic PAKKT method (in particular, Algorithm 1) that satisfies the lower level strict complementarity, then x^* is a KKT point of (MPCC).*

4.2 Boundedness of the dual sequences generated by the method

An important consequence of the above discussion is that the sequences of Lagrange multipliers estimates associated with a PAKKT sequence are bounded whenever quasinormality takes place at the limit point x^* . More specifically, we have the following result:

Theorem 4.3. *Let $\{x^k\}$ be a PAKKT sequence for (P) with associated dual sequence $\{(\lambda^k, \mu^k)\}$. If $x^* = \lim_k x^k$ satisfies quasinormality, then the dual sequence is bounded.*

Proof. Let us define $\delta_k = \|(1, \lambda^k, \mu^k)\|_\infty$ for all k , and suppose that $\{\delta_k\}$ is unbounded. By (7) and (8) we have

$$\lim_k \frac{\lambda_i^k}{\delta_k} \neq 0 \quad \Rightarrow \quad \lambda_i^k h_i(x^k) > 0, \quad \forall k \quad (29)$$

and

$$\lim_k \frac{\mu_j^k}{\delta_k} \neq 0 \quad \Rightarrow \quad \mu_j^k g_j(x^k) > 0, \quad \forall k \quad (30)$$

for all $i = 1, \dots, m$ and $j = 1, \dots, p$. By the definition of δ_k , at least one of the left-hand side limits of (29) or (30) is nonzero. Furthermore, condition (5) guarantees

$$\nabla_x L(x^k, \lambda^k, \mu^k) = \nabla f(x^k) + \nabla h(x^k) \lambda^k + \nabla g(x^k) \mu^k \rightarrow 0, \quad (31)$$

Thus, dividing (31) by δ_k and taking the limit, the quasinormality condition at x^* is violated. This concludes the proof. \square

Theorem 4.3 says that any PAKKT method generates a bounded sequence of Lagrange multipliers estimates under quasinormality. In particular, the dual sequences generated by Algorithm 1, namely $\{\lambda^k = \bar{\lambda}^k + \rho_k h(x^k)\}$ and $\{\mu^k = (\bar{\mu}^k + \rho_k g(x^k))_+\}$ (see step 2), are bounded under quasinormality.

Corollary 4.3. *Let $\{x^k\}$ be the sequence generated by Algorithm 1 applied to (P). Suppose that $x^* \in X$ is a feasible accumulation point of $\{x^k\}$ with associated infinite index set K , i.e., $\lim_{k \in K} x^k = x^*$. Also, suppose that x^* satisfies quasinormality. Then the associated dual sequences $\{\lambda^k\}_{k \in K}$ and $\{\mu^k\}_{k \in K}$ computed in the step 2 are bounded.*

Proof. By the proof of Theorem 4.1, if the dual sequence $\{(\lambda^k, \mu^k)\}_{k \in K}$ generated by Algorithm 1 is unbounded then the method in fact generates a PAKKT sequence with unbounded associated dual sequence. Thus, the statement follows from Theorem 4.3. \square

The boundedness of the multipliers estimates has a practical consequence in the stability of Algorithm 1. In fact, we can expect, at least in theory, that, under the quasinormality CQ, the multipliers generated by the algorithm do not grow indefinitely, avoiding numerical instabilities. In particular, the boundedness of μ^k in (15) tends to force the nullity of V^k if μ_{\max} is sufficiently large to encompass all μ^k 's, leading to the choice $\rho_{k+1} = \rho_k$ in step 3. It is worth noticing that the interior point method implemented in the popular IPOPT package tends to generate unbounded multipliers even for linear problems of the NETLIB collection [20].

Evidently, Corollary 4.3 (and more generally Theorem 4.3) is valid for any CQ stronger than quasinormality, like pseudonormality, LICQ, MFCQ, CPLD, CRCQ and linear constraints (see Figure 4). It is surprising that the authors of [6] did not prove this statement for CPLD. Actually, we have also not established this result in the first publicly available version of this paper, although it is a natural consequence of our theory. Very recently, and citing this earlier version, Bueno, Haeser and Rojas reported this fact in a more general context, namely, of the generalized Nash equilibrium problems (see [16, Theorem 6.3]). In this sense, it is not the first time that Corollary 4.3 appears in the literature.

Finally, it is worth mentioning that, under the MPCC-quasinormality condition, Theorem 4.3 and lemma 4.1 imply the boundedness of MPCC-multipliers estimates (particularly (26)) generated by Algorithm 1 when applied to MPCCs. To the best of our knowledge, this type of result for augmented Lagrangian methods has not been previously established in the literature. We summarize this below.

Corollary 4.4. *Let $\{x^k\}$ be the sequence generated by Algorithm 1 applied to (MPCC). Suppose that $x^* \in X$ is a feasible accumulation point of $\{x^k\}$ with associated infinite index set K , and for which MPCC-quasinormality is satisfied. Then the associated sequence of the usual Lagrange multipliers $\{(\lambda^k, \mu^k, \gamma^{H,k}, \gamma^{G,k}, \gamma^{0,k})\}_{k \in K}$ computed in the step 2 is bounded. In particular, the associated sequence of MPCC-multipliers $\{(\lambda^k, \mu^k, \tilde{\gamma}^{H,k}, \tilde{\gamma}^{G,k})\}_{k \in K}$, where*

$$\tilde{\gamma}_i^{H,k} = \gamma_i^{H,k} - \gamma_i^{0,k} G_i(x^k) \quad \text{and} \quad \tilde{\gamma}_i^{G,k} = \gamma_i^{G,k} - \gamma_i^{0,k} H_i(x^k)$$

for all k and $i = 1, \dots, s$, is bounded.

5 Conclusions and future work

A new sequential optimality condition, called *Positive Approximate KKT* (PAKKT), is defined in the present work. The main goal of this new condition is to take into account the control of the dual sequence inspired in the enhanced Fritz-John optimality conditions developed by Hestenes [22]. This control is related to the external penalty theory and, therefore, it brings the quasinormality constraint qualification to the context. As the Powell-Hestenes-Rockafellar (PHR) augmented Lagrangian method has an intrinsic connection with the pure external penalty method, we were able to prove that this practical method converges to KKT points under the quasinormality constraint qualification, a new result in the literature. In addition, we were able to prove the boundedness of Lagrange multipliers estimates generated by the method.

We also provided the strict constraint qualification related to the PAKKT optimality condition, called PAKKT-regular, and we proved that it is less stringent than both quasinormality and the cone continuity property (see [8]). As a consequence, we generalized all previous theoretical convergence results for the PHR augmented Lagrangian method. In fact, we proved that this method reaches the new PAKKT points. These points are stronger than the Approximate KKT (AKKT) notion defined in [3], which had been used to analyze the convergence of this popular technique [3, 15]. In this sense, we highlighted the class of degenerate Mathematical Programs with Complementarity Constraints (MPCCs), in which the gap between AKKT and PAKKT points is drastic. Some new results in the MPCC-context were also obtained. Furthermore, we presented the relationship between PAKKT and other known sequential optimality conditions in the literature.

From the practical point of view, the fact that the PAKKT condition is defined independently of a particular method is very important to generalize convergence properties of existent algorithms, and this will be a topic for a future work. In particular, as PAKKT describes the behavior of the classical external penalty approach, it is reasonable to expect that other methods based on this technique will be able to achieve PAKKT points.
