Further Development in Convex Conic Reformulation of Geometric Nonconvex Conic Optimization Problems

Naohiko Arima, Sunyoung Kim, Masakazu Kojima

August 11, 2023

Abstract

A geometric nonconvex conic optimization problem (COP) was recently proposed by Kim, Kojima and Toh as a unified framework for convex conic reformulation of a class of quadratic optimization problems and polynomial optimization problems. The nonconvex COP minimizes a linear function over the intersection of a nonconvex cone $\mathcal{K}$, a convex subcone $\mathcal{J}$ of the convex hull $\text{co}(\mathcal{K})$ of $\mathcal{K}$, and an affine hyperplane with a normal vector $\mathbf{H}$. Under the assumption $\text{co}(\mathcal{K} \cap \mathcal{J}) = \mathcal{J}$, the original nonconvex COP in their paper was shown to be equivalently formulated as a convex conic program by replacing the constraint set with the intersection of $\mathcal{J}$ and the affine hyperplane. This paper further studies some remaining issues, not fully investigated there, such as the key assumption $\text{co}(\mathcal{K} \cap \mathcal{J}) = \mathcal{J}$ in the framework. More specifically, we provide three sets of necessary-sufficient conditions for the assumption. As an application, we propose a new wide class of quadratically constrained quadratic programs with multiple nonconvex equality and inequality constraints that can be solved exactly by their semidefinite relaxation.

Key words. Convex conic reformulation, geometric conic optimization problem, quadratically constrained quadratic program, polynomial optimization problem, positive semidefinite cone, exact semidefinite relaxation.

1 Introduction

Convex conic reformulation of a geometric nonconvex conic optimization problem (COP) was studied by Kim, Kojima and Toh in [14] as a unified framework for completely positive programming reformulation of a wide class of nonconvex quadratic optimization problems.
(QOPs). This class includes a wide range of QOPs, such as QOPs over the standard simplex \([5]\), maximum stable set problems \([8]\), graph partitioning problems \([18]\) and quadratic assignment problems \([8]\), and its extension to polynomial optimization problems (POPs) \([2, 3, 16]\). The class of QOPs also covers Burer’s class of QOPs with linear equality and complementarity constraints in nonnegative and binary variables \([7]\). Their geometric nonconvex COP denoted by \(\text{COP}(\mathbb{K} \cap \mathbb{J})\) below is quite simple, but it is powerful enough to capture the basic essentials to investigate convex conic reformulation of general nonconvex COPs. In fact, it minimizes a linear function in a finite dimensional vector space \(V\) over the intersection of three geometrically represented sets, a nonconvex cone \(\mathbb{K}\), a convex subcone \(\mathbb{J}\) of the convex hull \(\text{co}\mathbb{K}\) of \(\mathbb{K}\), and an affine hyperplane with a normal vector \(H\). The framework was also used in the recent paper \([9]\) which proposed a large class of quadratically constrained quadratic programs with stochastic data. See also \([6]\).

Let \(V\) be a finite dimensional vector space endowed with the inner product \(\langle A, B \rangle\) for every pair of \(A\) and \(B\) in \(V\). Let \(O \neq H \in V\) and \(Q \in V\) be fixed. For every (but not necessarily convex) cone \(\mathbb{C}\), let \(\text{COP}(\mathbb{C})\) denote the conic optimization problem (COP) of the form

\[
\zeta_p(\mathbb{C}) = \inf \left\{ \langle Q, X \rangle : X \in \mathbb{C}, \langle H, X \rangle = 1 \right\}.
\]

If COP(\(\mathbb{C}\)) is infeasible, we let \(\zeta_p(\mathbb{C}) = \infty\). By replacing \(\mathbb{C}\) by its convex hull \(\text{co}\mathbb{C}\), we obtain a convex relaxation COP(co\(\mathbb{C}\)) of the problem. When the original nonconvex COP(\(\mathbb{C}\)) and the relaxed convex COP(co\(\mathbb{C}\)) share a common optimal value, i.e., \(\zeta_p(\mathbb{C}) = \zeta_p(\text{co}\mathbb{C})\), the convex COP is called a convex conic reformulation of the nonconvex COP.

A nonconvex COP introduced in \([14]\) is described as

\[
\text{COP}(\mathbb{K} \cap \mathbb{J}): \quad \zeta_p(\mathbb{K} \cap \mathbb{J}) = \inf \left\{ \langle Q, X \rangle : X \in \mathbb{K} \cap \mathbb{J}, \langle H, X \rangle = 1 \right\}
\]

under the following conditions:

(A) \(\mathbb{K}\) is a nonempty cone (but not necessarily convex) in \(V\) and \(-\infty < \zeta_p(\mathbb{K} \cap \mathbb{J}) < \infty\) (i.e., COP(\(\mathbb{K} \cap \mathbb{J}\)) is feasible and has a finite optimal value).

(B) \(\mathbb{J}\) is a convex cone contained in \(\text{co}\mathbb{K}\) such that \(\text{co}(\mathbb{K} \cap \mathbb{J}) = \mathbb{J}\).

Among the theoretical results established in \([14]\), we mention the following equivalence result (see \([14\, \text{Theorem 3.1}],\, [11\, \text{Theorem 5.1}]\) for more details).

**Theorem 1.1.** Assume that Conditions (A) and (B) are satisfied. Then,

\[
\begin{aligned}
-\infty < \zeta_p(\mathbb{J}) < \infty, \\
\iff
-\infty < \zeta_p(\mathbb{K} \cap \mathbb{J}) = \zeta_p(\mathbb{J}) < \infty
\end{aligned}
\]

\(\implies\) (i.e., COP(\(\mathbb{J}\)) is a convex reformulation of COP(\(\mathbb{K} \cap \mathbb{J}\))).

First, we briefly discuss some remaining issues, which were not thoroughly studied in \([14]\), (a), (b) and (c) described below.

(a) The feasibility preserving property \([24]\). COP(co\(\mathbb{C}\)) is feasible if and only if COP(\(\mathbb{C}\)) with a nonconvex cone \(\mathbb{C} \subset V\) is feasible (Section 2.1). By this property, we can remove the requirement \(-\infty < \zeta_p(\mathbb{K} \cap \mathbb{J}) < \infty\) from Condition (A) for the equivalence relation \([2]\) (Corollary 2.2).
(b) Strong duality of the reformulated convex COP (Section 2.2). The duality of COP(\mathcal{J}) was not used in \cite{14}, but is surely important not only for its further theoretical development, but also possible numerical methods for solving COP(\mathcal{J}). Here the dual of COP(\mathcal{J}) is given by

\[ DCOP(\mathcal{J}) : \zeta_d(\mathcal{J}) = \sup \{ t : Q - Ht \in \mathcal{J}^* \}, \tag{3} \]

where \( \mathcal{J}^* = \{ Y \in \mathcal{V} : \langle X, Y \rangle \geq 0 \text{ for every } X \in \mathcal{J} \} \) (the dual cone of \( \mathcal{J} \)).

(c) The existence of a common optimal solution of a nonconvex COP and the reformulated convex COP (Section 2.3). In theory, \( \zeta_p(\mathcal{K} \cap \mathcal{J}) = \zeta_p(\mathcal{J}) \) does not ensure that COP(\mathcal{K} \cap \mathcal{J}) and COP(\mathcal{J}) have a common optimal solution. We present a sufficient condition for them to have a common optimal solution using the dual of COP(\mathcal{J}).

If \( \mathcal{J} \) is a face of co\mathcal{K}, then co(\mathcal{K} \cap \mathcal{J}) = \mathcal{J} \) (Condition (B)) is satisfied. This case was thoroughly studied and played an essential role in convex conic reformulation of QOPs and POPs in \cite{14}. Another case mentioned in \cite{14} Lemma 2.1 (iv) for Condition (B) is: \( \mathcal{J} \) is the convex hull of the union of (possibly infinitely many) faces of co\mathcal{K}. But neither its implication nor its application was discussed there. In Section 3 of this paper, we introduce the family \( \hat{\mathcal{F}}(\mathcal{K}) \) of all \( \mathcal{J} \) which satisfy co(\mathcal{K} \cap \mathcal{J}) = \mathcal{J}, \) and study its fundamental properties. In particular, we establish the following characterization of \( \hat{\mathcal{F}}(\mathcal{K}) \).

**Theorem 1.2.**

(i) \( \mathcal{J} \in \hat{\mathcal{F}}(\mathcal{K}) \) iff \( \mathcal{J} = \text{co}\mathcal{K}' \) for some cone \( \mathcal{K}' \subset \mathcal{K} \).

(ii) \( \mathcal{J} \in \hat{\mathcal{F}}(\mathcal{K}) \) iff \( \mathcal{J} = \text{co}(\bigcup \mathcal{F}) \) for some \( \mathcal{F} \subset \hat{\mathcal{F}}(\mathcal{K}) \).

(iii) Assume that co(\mathcal{K} \cap \mathcal{J}) and \( \mathcal{J} \) are closed and that \( H \in \text{int}(\mathcal{J}^*) \). Then \( \mathcal{J} \in \hat{\mathcal{F}}(\mathcal{K}) \) iff

\[ \zeta_p(\mathcal{K} \cap \mathcal{J}) = \zeta_p(\mathcal{J}) \text{ for every } Q \in \mathcal{V}. \]

A proof is given in Section 3.3. Based on assertion (ii), we discuss a decomposition of the convex reformulation COP(\text{co}(\bigcup \mathcal{F})) of COP(\mathcal{K} \cap (\text{co}(\bigcup \mathcal{F}))) with \( \mathcal{F} \subset \hat{\mathcal{F}}(\mathcal{K}) \) into the convex reformulations COP(\mathcal{F}) of COP(\mathcal{K} \cap \mathcal{F}) (\mathcal{F} \in \mathcal{F}) (Theorem 3.6).

In Section 4 we focus on the case where \( \mathcal{K} \) is represented as \( \mathcal{K} = \{ xx^T : x \in \mathbb{R}^n \} \subset S^n \) (the space of \( n \times n \) symmetric matrices) and \( \mathcal{J} \) by multiple inequalities such that \( \mathcal{J} = J_- \equiv \{ X \in \text{co}\mathcal{K} : \langle B_k, X \rangle \leq 0 \text{ for every } 1 \leq k \leq m \} \) for some \( B_k \in S^n \) (1 \( \leq k \leq m \)). In this case, co\mathcal{K} forms the cone \( S^n_+ \) of positive semidefinite matrices in \( S^n \), and COP(\mathcal{J}_-) serves as a semidefinite programming (SDP) relaxation of COP(\mathcal{K} \cap \mathcal{J}_-), which can be regarded as a quadratically constrained quadratic program (QCQP) with nonconvex inequality constraints \( x^T B_k x \leq 0 \) (1 \( \leq k \leq m \)) and an equality constraint \( x^T H x = 1 \). By using Theorem 1.2 (iii) and \cite{23} Lemma 2.2, we establish that \( \mathcal{J}_- \equiv \{ X \in \text{co}\mathcal{K} : \langle B_k, X \rangle \leq 0 \text{ for every } 1 \leq k \leq m \} \subset \hat{\mathcal{F}}(\mathcal{K}) \) if condition

\[ \mathcal{J}_0(B_k) \equiv \{ X \in S^n_+ : \langle B_k, X \rangle = 0 \} \subset \mathcal{J}_- \text{ (1 \( \leq k \leq m \))} \tag{4} \]

is satisfied. This result leads to a wide class of QCQPs with multiple nonconvex constraints, COP(\mathcal{K} \cap \mathcal{J}_-) with \( B_k \in S^n \) (1 \( \leq k \leq m \)) satisfying condition \( \mathcal{J}_0 \), that can be solved by their SDP relaxation COP(\mathcal{J}_-). See Figure 1 for a geometrical image of condition \( \mathcal{J}_0 \). We know that if \( X \) is a common optimal solution of COP(\mathcal{K} \cap \mathcal{J}_-) and its SDP relaxation COP(\mathcal{J}_-), then rank\( X = 1 \). In case (a), every extreme ray of \( \mathcal{J}_- \) on which COP(\mathcal{J}_-) can
Figure 1: Geometrical illustrations for condition (4) with \( m = 3 \). (a) illustrates a case where (4) is satisfied, and (b) a case where (4) is not satisfied. Here \( \mathbb{J}_-(B_k) = \{ X \in S^n_+ : \langle B_k, X \rangle \leq 0 \} \) (1 \( \leq k \leq m \)) and \( \mathbb{J}_- = \cap_{k=1}^3 \mathbb{J}_-(B_k) \).

 attain an optimal solution \( X \) lies on the boundary of \( S^n_+ \) whose extreme rays are known to be generated by rank-1 matrices. In case (b), \( \mathbb{J}_- \) includes an extreme ray not included on the boundary of \( S^n_+ \); hence such an extreme ray may be generated by a matrix with rank greater than 1. Thus, condition (4) is quite natural to ensure the equivalence of \( \text{COP}(\mathbb{J}_-) \) and its SDP relaxation \( \text{COP}(\mathbb{K} \cap \mathbb{J}_-) \) for any \( Q \in S^n \). We also see that \( \mathbb{J}_- = \text{co}\mathbb{K}' \) for some \( \mathbb{K}' \subseteq \mathbb{K} \) in case (a) but \( \mathbb{J}_- \neq \text{co}\mathbb{K}' \) for any \( \mathbb{K}' \subseteq \mathbb{K} \) in case (b). Therefore, by Theorem 1.2 (i), \( \mathbb{J}_- \in \hat{\mathcal{F}}(\mathbb{K}) \) in case (a) but \( \mathbb{J}_- \notin \hat{\mathcal{F}}(\mathbb{K}) \) in case (b).

1.1 Contribution of the paper and related literature

We summarize two main contributions of the paper: The first contribution is more precise characterizations of Condition (B), which plays a central role in the theory of convex conic reformulation of geometric COPs, as shown in Theorem 1.2. This contribution together with (a), (b) and (c) above makes the theory solid and more applicable to a wide range of problems.

The other, a more important contribution, is that we present a new wide class of QCQPs with multiple nonconvex constraints \( \langle B_k, X \rangle \leq 0 \) (1 \( \leq k \leq m \)) and \( \langle H, X \rangle = 1 \) that can be solved exactly by their SDP relaxation. The equivalence of QCQPs and their SDP relaxation was studied extensively in many papers including [4, 10, 11, 17, 20, 21, 22, 23, 25]. The classes of QCQPs studied there can be classified into two categories. The first class requires some special sign patterns of the data matrices involved in QCQPs [4, 11, 20, 25]. The studies on the second class have been based on the requirement that the number of nonconvex constraints is at most two [23] and some additional assumption on the quadratic functions involved in the constraint [10, 17, 21, 22, 23]. Trust-region subproblems of nonlinear programs have been frequently studied in relation to the second class. Our class of QCQPs is also related to the second class, but represents a much wider class than them in the sense that QCQPs can involve any finite number of nonconvex constraints and condition (4) required is quite general and also natural to ensure the equivalence of QCQPs and their SDP relaxation (see Figure 1).
1.2 Outline of the paper

In Section 2, we discuss the three issues (a), (b) and (c) mentioned above in detail. In Section 3, we present some fundamental properties on $\mathcal{F}(K)$, and prove Theorem 1.2. We also discuss decompositions of a nonconvex COP and its convex conic reformulation based on Theorem 1.2 (ii). In Section 4, we present the class of QCQPs with multiple nonconvex inequality and equality constraints that can be reformulated as their SDP relaxation. Some representative QCQP examples in this class are presented. We conclude in Section 5 with remarks on the features of the geometric nonconvex COP($K \cap J$) as a unified framework, and its possible application to the completely positive cone.

1.3 Notation and symbols

Throughout the paper, we assume

$$V = \text{a finite dimensional vector (linear) space}$$

with the inner product $\langle A, B \rangle$ for every $A, B \in V$,

$$K = \text{a cone in } V,$$

$$Q \in V, H \in V.$$  

Here we say that $C \subset V$ is a cone, which is not necessarily convex nor closed, if $\lambda A \in C$ for every $A \in C$ and $\lambda \geq 0$. For every subset $S$ of $V$, int$S$ and relint$S$ denote the interior of $S$ with respect to the subspace spanned by $S$, respectively. Let $coC$ denote the convex hull of a cone $C \subset V$. Since $C$ is a cone, we see that $coC = \{ \sum_{k=1}^{m} X^k : X^k \in C (k = 1, \ldots, m) \}$ for some $m$. We note that a cone $C$ is convex if $X = \sum_{k=1}^{m} X^k \in C$ whenever $X^k \in C (k = 1, \ldots, m)$. We denote $\{ Y \in V : \langle X, Y \rangle \geq 0 \text{ for every } X \in C \}$ by $C^*$, which forms a closed convex cone in $V$. We call $C^*$ the dual of $C$. Let $C$ be a convex cone in $V$. A convex cone $F \subset C$ is a face of $C$ if $X^k \in F (1 \leq k \leq m)$ whenever $X = \sum_{k=1}^{m} X^k \in F$ and $X^k \in C (1 \leq k \leq m)$. An extreme ray of $C$ is a face which spans a 1-dimensional linear subspace of $V$. For a family $S$ of subsets of $V$ and a subset $T$ of $V$, $\bigcup S$ denotes the union of all $U \in S$, i.e., $\bigcup S = \bigcup_{U \in S} U$, and $T \cap S = \{ T \cap U : U \in S \}$.

Let $\mathbb{R}^n$ denotes the $n$-dimensional linear space of column vectors $x = (x_1, \ldots, x_n)$, $\mathbb{S}^n$ the linear space of the $n \times n$ symmetric matrices, and $\mathbb{S}^n_+$ the cone of $n \times n$ positive semidefinite symmetric matrices. $\| x \|$ denotes the Euclidean norm of each $x \in \mathbb{R}^n$, and $\| X \|$ the Frobenius norm of each $X \in \mathbb{S}^n$.

For every cone $C$, we recall that COP$(C)$ denotes the conic optimization problem of the form (1) with the optimal value $\zeta_p(C)$, where $Q \in V$ and $H \in V$ are fixed. For every convex cone $J \subset coK$, DCOP$(J)$ denotes the dual of COP$(J)$ with the optimal value $\zeta_d(J)$ given by (3). We assume that $\zeta_p(C) = \infty$ ($\zeta_d(J) = -\infty$) if COP$(C)$ (DCOP$(J)$) is infeasible.

2 Some remaining issues

In this section, we discuss issues (a) and (b) and (c).
2.1 The feasibility preserving property — (a)

The property that the nonconvex problem is feasible iff its convex relaxation is feasible is called feasibility preserving. This property was fully studied in [24] for convex relaxation of nonconvex QOPs. We present a simple proof that our geometric framework is feasibility preserving.

**Lemma 2.1.** Let $C$ be a nonempty cone in $V$. COP($C$) is feasible (infeasible, respectively) iff COP(co$C$) is feasible (infeasible, respectively).

**Proof.** It suffices to show that if COP(co$C$) is feasible, then COP($C$) is feasible. Let $X$ be a feasible solution of COP(co$C$). Then, there exist $X_k \in C$ $(1 \leq k \leq m)$ such that $X = \sum_{k=1}^{m} X_k$. Since $1 = \langle H, X \rangle = \langle H, \sum_{k=1}^{m} X_k \rangle$, $\langle H, X_k \rangle > 0$ for some $k$. Let $\hat{X} = X_k / \langle H, X_k \rangle$. Then $\hat{X} \in C$ and $\langle H, \hat{X} \rangle = 1$. Hence $\hat{X}$ is a feasible solution of COP(co$C$).

By Lemma 2.1 we can weaken Condition (A).

**(A)'** $K$ is a nonempty (not necessarily convex) cone in $V$.

**Corollary 2.2.** Assume Conditions (A)' and (B). Then (2) holds.

**Proof.** If $-\infty < \zeta_p(J) < \infty$, then $-\infty < \zeta_p(J) \leq \zeta_p(K \cap J) < \infty$ holds by Lemma 2.1. Hence Condition (A) is satisfied. Therefore, (2) holds by Theorem 1.1.

By the corollary and the lemma above, we know under Conditions (A)' and (B) that if COP($J$) attains the finite optimal value $\zeta_p(J)$, then $\zeta_p(K \cap J) = \zeta_p(J)$, and that if COP($J$) is infeasible, then so is COP($K \cap J$).

2.2 Strong duality of COP($J$) — (b)

As a straightforward application of [13, Theorem 2.1] to the primal-dual pair COP($J$) and DCOP($J$) with $H \in J^*$, we obtain the following result.

**Theorem 2.3.** Assume that $J$ is a closed convex cone in $V$, $H \in J^*$ and that $-\infty < \zeta_p(J) < \infty$ or $-\infty < \zeta_d(J) < \infty$. Then the following assertions hold.

(i) $-\infty < \zeta_p(J) = \zeta_d(J) < \infty$ holds.

(ii) Dual DCOP($J$) has an optimal solution.

(iii) The set of optimal solutions of primal COP($J$) is nonempty and bounded iff $Q - Ht \in \text{int} J^*$ for some $t \in \mathbb{R}$.

(iv) The set of optimal solutions of primal COP($J$) is nonempty and unbounded if $J$ is not pointed and $Q - Ht \in \text{relint} J^*$ for some $t \in \mathbb{R}$.

We note that the condition “$J$ is closed” is natural when the existence of an optimal solution of COP($J$) is discussed, and the condition $H \in J^*$ holds naturally when QOPs and POPs are converted into COP($K \cap J$). See [14, Sections 3.2, 4 and 5].
2.3 Existence of a common optimal solution of COP(J) and COP(K ∩ J) — (c)

If \( X \) is an optimal solution of COP(K ∩ J), then the identity \( \zeta_p(K ∩ J) = \zeta_p(J) \) ensures that \( X \) is also an optimal solution of COP(J) since \( K ∩ J \subseteq J \). In general, however, a nonconvex (or even convex) COP may have no optimal solution even when it has a finite optimal value. See, for example, [12, Section 4]. The following theorem provides a sufficient condition for a common optimal solution of COP(K ∩ J) and COP(J).

**Theorem 2.4.** Assume that \( K \) is a closed cone in \( V \), \( J \subseteq coK \) is a closed convex cone satisfying \( co(K ∩ J) = J \), COP(K ∩ J) is feasible, \( H \in J^* \), and that \( Q - Ht \in int J^* \) (the interior of \( J^* \)) for some \( t \in \mathbb{R} \). Then,

\[
-\infty < \zeta_d(J) = \zeta_p(J) < \infty, \\
COP(K ∩ J) \text{ and } COP(J) \text{ have a common optimal solution,} \\
DCOP(J) \text{ has an optimal solution.}
\]

The strict feasibility of DCOP(J) (i.e., Slater’s constraint qualification \( Q - Ht ∈ int J^* \) for some \( t \)) is assumed here for the existence of solutions of COP(K ∩ J) and COP(J). It should be emphasized that none of the finite optimal values for COP(K ∩ J), COP(J) and DCOP(J) is assumed in advance.

**Proof of Theorem 2.4.** We prove that COP(J) and COP(K ∩ J) have a common optimal solution \( X^* \). Choose a feasible solution \( \overline{X} ∈ K ∩ J \) of COP(K ∩ J). We consider the level sets of COP(K ∩ J) and COP(J) given by

\[
S(K ∩ J) \equiv \{ X ∈ K ∩ J : \langle H, X \rangle = 1, \langle Q, X \rangle ≤ \langle Q, \overline{X} \} \}, \\
S(J) \equiv \{ X ∈ J : \langle H, X \rangle = 1, \langle Q, X \rangle ≤ \langle Q, \overline{X} \} \}.
\]

Then \( \overline{X} ∈ S(K ∩ J) \subseteq S(J) \). Since \( K \) and \( J \) are closed, both \( S(K ∩ J) \) and \( S(J) \) are closed. We will show that \( S(J) \) is bounded. Assume on the contrary that \( S(J) \) is unbounded. Then, there exists a sequence \( \{ X_k ∈ S(J) \} \) such that \( \| X_k \| → ∞ \) as \( k → ∞ \). We may assume without loss of generality that \( X_k / \| X_k \| ∈ \overline{J} \) converges to \( \Delta X ∈ \overline{J} \) such that

\[
\Delta X ∈ J, \| \Delta X \| = 1, \langle H, \Delta X \rangle = 0, \langle Q, \Delta X \rangle ≤ 0.
\]

By \( O \neq \Delta X ∈ J \) and the assumption that \( Q - Ht ∈ int J^* \) for some \( t ∈ \mathbb{R} \), we see that

\[
0 < \langle Q - Ht, \Delta X \rangle = \langle Q, \Delta X \rangle - \langle H, \Delta X \rangle ≤ 0,
\]

which is a contradiction. Hence we have shown that both \( S(J) \) and \( S(K ∩ J) \) are closed and bounded. Therefore, both COP(J) and COP(K ∩ J) have optimal solutions, say \( \hat{X} \) and \( X^* \), respectively. It follows that \( -\infty < \zeta_p(J) ≤ \zeta_p(K ∩ J) = \langle Q, X^* \rangle < ∞ \). Since the equivalence relation (2) holds by Corollary 2.2, we see that \( \zeta_p(J) = \zeta_p(K ∩ J) = \langle Q, X^* \rangle \). Therefore, \( X^* \) is a common optimal solution of COP(J) and COP(K ∩ J). All other assertions in (5) follow from Theorem 2.3.

\[\square\]
3 On Condition (B)

If \( J \) is a face of \( \text{co}K \) or the convex hull of the union of a family of faces of \( \text{co}K \), then Condition (B) holds. The former case was studied throughly in \([14]\) for its applications to convex conic reformulation of QOPs and POPs. In this section, we further investigate fundamental properties of Condition (B).

To characterize Condition (B), we define

\[
\hat{F}(K) = \left\{ J : J \text{ satisfies Condition (B), i.e., } J \text{ is a convex cone in } \text{co}K \text{ satisfying } \text{co}(K \cap J) = J \right\}.
\]

3.1 Illustrative examples

We show 4 examples of \( J \in \hat{F}(K_r) \) for \( K_r \) (\( r = 1, 2 \)) whose convex hull forms a common semicircular cone in \( V = \mathbb{R}^3 \) in Figure 1, where a 2-dim. section of \( K_r \) is illustrated (\( r = 1, 2 \)). We identify an extreme ray (or a 2-dimensional face, respectively) of the semicircular cone \( \text{co}K_r \) with an extreme point (or a 1-dimensional face, respectively) of the section of \( \text{co}K_r \) corresponding to it (\( r = 1, 2 \)). \( K_1 \) consists of all extreme rays of the semicircular cone, which correspond to the half circle. \( K_2 \) includes the 2-dim. face of the semicircular cone, which corresponds to the line segment \([e, f]\), in addition to all extreme rays. Note that the common \( K = K_1 \) is used for Examples 3.1, 3.2 and 3.3, and \( K = K_2 \) for Example 3.4. In each example, it is easy to verify that assertions (i), (ii) and (iii) of Theorem 3.5 with \( K = K_r \) hold.

Example 3.1. If we choose 3 distinct extreme points \( a, b, c \) on the half circle as in Figure 1 (a), their convex hull \( J_1 \in \hat{F}(K_1) \) forms a closed polyhedral cone. Letting \( F_1 = \{ a, b, c \} \), we can write \( J_1 = \text{co}( \bigcup F_1 ) \).

Example 3.2. Let \( F_2 \) be the union of all extreme points contained in the arc \( a \) to \( b \) along the half circle and an extreme point \( c \) (see Figure 1 (b)), their convex hull \( J_2 = \text{co}( \bigcup F_2 ) \) forms a non-polyhedral closed convex cone. We see that \( J_2 \in \hat{F}(K_1) \).

Example 3.3. We modify Example 3.2 by letting \( F_3 = F_2 \setminus \{ b \} \) as in Figure 1 (c). Then \( J_3 = \text{co}( \bigcup F_3 ) \in \hat{F}(K_1) \). In this case, \( J_3 \) is not closed. Hence, this example shows that \( \hat{F}(K_1) \) contains non-closed convex cone in general.

Example 3.4. In this example, \( K_2 \) includes the 2-dim. face of \( \text{co}K_2 \), which corresponds to the line segment \([e, f]\) of its section as in Figure 1 (d). Let \( F_4 \) be the union of all extreme points contained in the arc \( a \) to \( b \) along the half circle and the semi-closed interval \([d, c]\) on \([e, f]\). Then \( J_4 = \text{co}( \bigcup F_4 ) \in \hat{F}(K_2) \). It should be noted that \( J_4 \in \hat{F}(K_2) \) cannot be generated in Examples 3.1, 3.2 and 3.3 since the 2-dim. face \([e, f]\) is not included in \( K_1 \).

3.2 Basic properties on \( \hat{F}(K) \)

We now show some fundamental properties on \( \hat{F}(K) \) including the ones observed in the examples above.

Theorem 3.5. The following assertions hold.

(i) \( F \in \hat{F}(K) \) for every face \( F \) of \( J \in \hat{F}(K) \).
Figure 2: A 2-dim. section of a 3-dim. semicircular cone \( \text{co}K \). (a) — Example 3.1, (b) — Example 3.2, (c) — Example 3.3 and (d) — Example 3.4. In (a), (b) and (c), each point on the solid half circle is identified with an extreme ray of the 3-dim. semicircular cone \( \text{co}K \). In (d), the line segment \([e, f]\) is identified with the 2-dim. face of the 3-dim. semicircular cone \( \text{co}K \).

(ii) \( J \cap F \in \hat{F}(K) \) for every face \( F \) of \( \text{co}K \) and \( J \in \hat{F}(K) \).

(iii) \( F \subset K \) for every extreme ray \( F \) of \( J \in \hat{F}(K) \).

(iv) \( \bigcup(K \cap F) \subset K \cap \text{co}(\bigcup F) \subset \text{co}(\bigcup F) \) for every \( F \subset \hat{F}(K) \).

(v) \( \text{co}(\bigcup(K \cap F)) = \text{co}(K \cap \text{co}(\bigcup F)) = \text{co}(\bigcup F) \) (hence \( \text{co}(\bigcup F) \in \hat{F}(K) \)) for every \( F \subset \hat{F}(K) \).

Proof of Theorem 3.5 (i): Let \( F \) be a face of \( J \in \hat{F}(K) \). \( \text{co}(K \cap F) \subset F \) is obvious. To show the converse inclusion relation, let \( X \in F \subset J = \text{co}(K \cap J) \). Then \( X = \sum_{k=1}^{m} X_k \) for some \( X_k \in K \cap J \) (1 \( \leq k \leq m \)). Since \( F \) is a face of \( J \), \( X_k \in F \) (1 \( \leq k \leq m \)). Hence, \( X \in \text{co}(K \cap F) \), and we have shown that \( \text{co}(K \cap F) \subset F \).

Obviously \( \text{co}K \in \hat{F}(K) \). Taking \( J = \text{co}K \) in (i), we see that \( F \in \hat{F}(K) \) for every face \( F \) of \( \text{co}K \). In particular, every extreme ray of \( \text{co}K \) is in \( \hat{F}(K) \).

Proof of Theorem 3.5 (ii): Assume that \( F \) is a face of \( \text{co}K \) and \( J \in \hat{F}(K) \). Then \( J \cap F \) is a convex cone and \( K \cap J \subset J \cap F \). Hence \( \text{co}(K \cap J) \subset J \cap F \) follows. To show that the converse inclusion \( \text{co}(K \cap J \cap F) \subset J \cap F \), suppose that \( X \in J \cap F \). Since \( J = \text{co}(K \cap J) \) by assumption, \( F \ni X = \sum_{k=1}^{m} X_k \) for some \( X_k \in K \cap J \subset \text{co}K \) (1 \( \leq k \leq m \)). Since \( F \) is a face of \( \text{co}K \), \( X_k \in F \) (1 \( \leq k \leq m \)). Hence \( X = \sum_{k=1}^{m} X_k \in \text{co}(K \cap J \cap F) \). Thus, we have shown \( \text{co}(K \cap J \cap F) = J \cap F \) and \( J \cap F \in \hat{F}(K) \).

Proof of Theorem 3.5 (iii): Assume that \( F \) is an extreme ray of \( J \in \hat{F}(K) \). To show \( F \subset K \), choose an arbitrary nonzero \( X \in F \). Then, \( X \in F \subset J = \text{co}(K \cap J) \) is represented as
\[ X = \sum_{k=1}^{m} X_k \] for some nonzero \( X_k \in K \cap J \) (\( k = 1, \ldots, m \)). Since \( F \) is an extreme ray of \( J \), nonzero \( X_k \) (\( 1 \leq k \leq m \)) all lie in the extreme ray \( F \). Hence, \( X = \lambda_k X_k \) for some \( \lambda_k > 0 \) (\( 1 \leq k \leq m \)). Let \( k \) be fixed. Since \( K \) is a cone and \( X_k \in K \), \( X = \lambda_k X_k \in K \). Thus, we have shown \( F \subseteq K \).

**Proof of Theorem 3.5 (iv):** Assume that \( F \subseteq F(K) \). Let \( X \in \bigcup(K \cap F) \). Then, there exists a \( J \in F \) such that \( X \in K \cap J \), which implies that \( X \in K \cap \text{co}(\bigcup F) \). Hence, \( \bigcup(K \cap F) \subseteq K \cap \text{co}(\bigcup F) \) holds. The second inclusion relation is straightforward.

**Proof of Theorem 3.5 (v):** Assume that \( F \subseteq F(K) \). By (iv), it suffices to show that \( \text{co}(\bigcup(K \cap F)) \supseteq \text{co}(\bigcup F) \). By assumption, \( \text{co}(\bigcup(K \cap F)) \supseteq (K \cap J) = J \) for every \( J \in F \). Hence, \( \text{co}(\bigcup(K \cap F)) \supseteq \bigcup F \) follows. Since \( \text{co}(\bigcup(K \cap F)) \) is a convex cone, we obtain that \( \text{co}(\bigcup(K \cap F)) \supseteq \text{co}(\bigcup F) \).

**3.3 Proof of Theorem 1.2**

‘only if part’ of (i): Assume that \( J \in F(K) \). Let \( K' = K \cap J \). Then, \( K' \) is a cone in \( K \) and \( J = \text{co}(K \cap J) = \text{co}K' \).

‘if part’ of (i): Assume that \( J = \text{co}K' \) for some cone \( K' \subset K \). Since \( J \) is convex, we obviously see that \( \text{co}(K \cap J) \subseteq J \). We also see from \( K' \subset K \) and \( \text{co}K' = J \) that \( K' = K \cap \text{co}K' \subset K \cap J \). Hence \( J = \text{co}K' \subset \text{co}(K \cap J) \). Therefore, we have shown \( \text{co}(K \cap J) = J \) and \( J \in F(K) \).

‘only if part’ of (ii): Assume that \( J \in F(K) \). Let \( F = \{J\} \). Then, \( F \subseteq F(K) \) and \( J = \text{co}J = \text{co}(\bigcup F) \) holds since \( J \) is convex.

‘if part’ of (ii): Assume that \( J = \text{co}(\bigcup F) \) for some \( F \subseteq F(K) \). Then, \( J \in F(K) \) follows from Theorem 3.5 (v)

‘only if part’ of (iii): Assume that \( J \in F(K) \). Let \( Q \in V \) be fixed arbitrarily. The feasible region \( \{X \in J : \langle Q, X \rangle = 0, \langle H, X \rangle = 1\} \) of COP(J) is either empty, or closed and bounded. If it is empty, then \( \zeta_p(J) = \zeta_{p}(K \cap J) = \infty \). Otherwise, it is nonempty, closed and bounded. Hence, \(-\infty < \zeta_p(J) < \infty \). Therefore, Conditions (A)’ and (B) hold, and \( \zeta_p(K \cap J) = \zeta_p(J) \) follows from Corollary 2.2

‘if part’ of (iii): Assuming \( J \notin F(K) \), we show that \(-\infty < \zeta_p(J) < \zeta_p(K \cap J) \notin F(K) \). It follows from \( J \notin F(K) \) that the closed convex cone \( \text{co}(K \cap J) \) is a proper subset of the closed convex cone \( J \). Hence, there exists a nonzero \( \tilde{X} = (\tilde{X}/\langle H, \tilde{X} \rangle) \in \bigcup(K \cap J) \subseteq \text{co}K \). Let \( \tilde{X} = X/\langle H, X \rangle \in J \left( \text{co}(K \cap J) \right) \subseteq \text{co}K \). Then, \( \tilde{X} \) is a feasible solution of COP(J) but not in the feasible region of COP(\( \text{co}(K \cap J) \)), i.e., \( \tilde{X} \notin S \equiv \{X \in \text{co}(K \cap J) : \langle H, X \rangle = 1\} \), where \( S \) is a closed and bounded convex set by the assumption \( H \in \text{int}K^* \). By the separation theorem of convex sets (see, for example, [19 Theorem 11.4.1]), there exist a \( Q \in V \) such that \( \langle Q, \tilde{X} \rangle < \inf(p, Q, X) : X \in S \rangle = \zeta_p(\text{co}(K \cap J)) \). Therefore, we obtain that

\[ -\infty < \zeta_p(J) \leq \langle Q, \tilde{X} \rangle < \zeta_p(\text{co}(K \cap J)) \leq \zeta_p(K \cap J). \]

**Given a convex cone \( C \), there are various ways to represent \( C \) as the convex hull of a nonconvex cone. For example, when the convex cone \( C \) is closed and pointed, \( C \) can be represented as the convex hull of the nonconvex cone consisting of the extreme rays of \( C \) [19 Theorem 18.5]. However, any face of \( C \) can be added to the nonconvex cone. Thus,**
the representation of $J$ in terms of the convex hull of a nonconvex cone $K$ is not unique. Theorem 1.2(i) shows the possibility of the ‘finest’ representation of $J \in \tilde{F}(K)$, and (ii) the possibility of various coarse representations of $J \in \tilde{F}(K)$. A similar observation can be applied to $\text{co}K$; two distinct nonconvex cones $K_1 \subset V$ and $K_2 \subset V$ induce a common convex set as their convex hull, $\text{co}K_1 = \text{co}K_2$, such that $\tilde{F}(K_1) \neq \tilde{F}(K_2)$. This fact has been observed in Examples 3.4.

### 3.4 Decompositions of COP($K \cap J$)

We now focus on Theorems 3.5(v) and 1.2(ii). Let $J \in \tilde{F}(K)$. Assume that $J$ is decomposed into $F \in \mathcal{F} \subset \mathcal{F}$ for some $\mathcal{F} \subset \mathcal{F}(K)$ such that $J = \text{co}(\cup \mathcal{F})$ as in Theorem 1.2(ii). In general, $\cup (K \cap \mathcal{F})$ could be a proper subset of $K \cap \text{co}(\cup \mathcal{F})$ by Theorem 3.5(iv). By Theorem 3.5(v), however, their convex hulls coincide with each other, and COP($\text{co}(K \cap \mathcal{F}))$ both induce a common convex relaxation, COP($\text{co}(\cup \mathcal{F}))$). We also know that each $F \in \mathcal{F}$ satisfies $\text{co}(K \cap F) = F$; hence COP($F$) is a convex relaxation of COP($K \cap F$). The following theorem summarizes the relations of the three pairs of COPs and their convex conic relaxation, COP($\cup (K \cap \mathcal{F}))$ and COP($\text{co}(\cup \mathcal{F}))$), COP($K \cap \text{co}(\cup \mathcal{F}))$ and COP($\text{co}(\cup \mathcal{F}))$, and COP($K \cap \mathcal{F})$ and COP($F$) $(F \in \mathcal{F})$. In particular, assertion (iii) of the theorem means that $\text{COP}(K \cap \mathcal{F})$ can be decomposed into the family of subproblems COP($K \cap F$), which is reformulated by COP($F$), $(F \in \mathcal{F})$.

**Theorem 3.6.** Assume that $\mathcal{F} \subset \tilde{F}(K)$ and that $-\infty < \zeta_p(\cup (\mathcal{F})) < \infty$. Then, the following assertions hold.

(i) $\zeta_p(\cup (K \cap \mathcal{F})) = \zeta_p(K \cap \text{co}(\cup \mathcal{F})) = \zeta_p(\cup (\mathcal{F}))$.

(ii) $\zeta_p(K \cap \mathcal{F}) = \zeta_p(\mathcal{F})$ $(\mathcal{F} \in \mathcal{F})$.

(iii) $\zeta_p(K \cap \text{co}(\cup \mathcal{F})) = \inf\{\zeta_p(K \cap F) : F \in \mathcal{F}\} = \inf\{\zeta_p(F) : F \in \mathcal{F}\}$.

**Proof.** (i) The pair of $K$ and $J = \text{co}(\cup \mathcal{F})$ satisfies Condition (A) by Lemma 2.1, and Condition (B) by Theorem 3.5(v). Hence $-\infty < \zeta_p(K \cap \text{co}(\cup \mathcal{F})) = \zeta_p(\cup (\mathcal{F})) < \infty$ by Theorem 1.1. We now prove the identity $\zeta_p(\cup (K \cap \mathcal{F})) = \zeta_p(\mathcal{F})$. First, we show that $-\infty < \zeta_p(\cup (K \cap \mathcal{F})) < \infty$. Since $\cup (K \cap \mathcal{F}) \subset K \cap \text{co}(\cup \mathcal{F})$ by Theorem 3.5(iv), we see that $-\infty < \zeta_p(K \cap \text{co}(\cup \mathcal{F})) \leq \zeta_p(\cup (K \cap \mathcal{F}))$. It remains to show that COP($\cup (K \cap \mathcal{F})$) is feasible. By Condition (A), there exists a feasible solution $\mathcal{X}$ of COP($K \cap \text{co}(\cup \mathcal{F})$), which satisfies $\mathcal{X} \in K$, $\mathcal{X} \in \text{co}(\cup \mathcal{F})$ and $\langle H, \mathcal{X} \rangle = 1$. From $\mathcal{X} \in \text{co}(\cup \mathcal{F})$, there exist $\mathcal{X}_k \in \cup \mathcal{F}$ ($1 \leq k \leq m$) such that $\mathcal{X} = \sum_{k=1}^m \mathcal{X}_k$. Since $1 = \langle H, \mathcal{X} \rangle = \sum_{k=1}^m \langle H, \mathcal{X}_k \rangle$, $\langle H, \mathcal{X}_k \rangle > 0$ for some $k$. Let $\mathcal{X} = \mathcal{X}_k/\langle H, \mathcal{X}_k \rangle$. Then $\mathcal{X} \in \text{co}(\cup \mathcal{F})$ for some $\mathcal{F} \in \mathcal{F}$ and $\langle H, \mathcal{X} \rangle = 1$, which implies that $\mathcal{X}$ is a feasible solution of COP($\cup (K \cap \mathcal{F})$). Hence, we have shown that $-\infty < \zeta_p(\cup (K \cap \mathcal{F})) < \infty$. Now, we observe that $\cup (K \cap \mathcal{F}) \cap \text{co}(\cup \mathcal{F}) = \cup (\mathcal{F})$ and that $\text{co}(\cup (K \cap \mathcal{F}) \cap \text{co}(\cup \mathcal{F})) = \text{co}(\cup (K \cap \mathcal{F})) = \text{co}(\cup \mathcal{F})$ by Theorem 3.5(v). Therefore $\zeta_p(\cup (K \cap \mathcal{F})) = \zeta_p(\cup (K \cap \mathcal{F}) \cap \text{co}(\cup \mathcal{F})) = \zeta_p(\cup \mathcal{F})$ follows from Theorem 1.1 with replacing $K$ by $\cup (K \cap \mathcal{F})$ and $J$ by $\text{co}(\cup \mathcal{F})$.

(ii) Let $\mathcal{F} \in \mathcal{F}$ be fixed arbitrary. Then, $\text{co}(K \cap F) = F$. By Lemma 2.1 if COP($K \cap F$) is infeasible then $\zeta_p(\mathcal{F}) = \zeta_p(F) = 1$. Otherwise, COP($F$) is feasible; hence $\zeta_p(F) < 1$. We also see that $-\infty < \zeta_p(\cup \mathcal{F}) \leq \zeta_p(F)$ from $\mathcal{F} \subset \text{co}(\cup \mathcal{F})$. By applying Corollary 2.2 with replacing $J$ by $F$, we obtain $\zeta_p(K \cap F) = \zeta_p(F)$. 

11
(iii) By (i) and (ii), it suffices to show \( \zeta_p(\bigcup(K \cap F)) = \inf \{ \zeta_p(K \cap F) : F \in F \} \). Since \( K \cap F \subset \bigcup(K \cap F) \) for every \( F \in F \), we see \( \zeta_p(\bigcup(K \cap F)) \leq \inf \{ \zeta_p(K \cap F) : F \in F \} \). To show the converse inequality, let \( \mathbf{X} \) be an arbitrary feasible solution of \( \text{COP}(\bigcup(K \cap F)) \) with the objective value \( \hat{\zeta}_p = \langle Q, \mathbf{X} \rangle \). Then \( \langle H, \mathbf{X} \rangle = 1 \) and \( \mathbf{X} \in \bigcup(K \cap F) \), i.e., \( \mathbf{X} \in K \cap F \) for some \( F \in F \). Hence \( \mathbf{X} \) is a feasible solution of \( \text{COP}(K \cap F) \). Therefore, \( \inf \{ \zeta_p(K \cap F) : F \in F \} \leq \zeta_p \). \( \square \)

4 A class of quadratically constrained quadratic programs with multiple nonconvex constraints

Throughout this section, we assume that \( K = \{ xx^T : x \in \mathbb{R}^n \} \). Thus, \( \text{co} K \) forms the positive semidefinite cone \( S^n_+ \) in the space \( S^n \) of \( n \times n \) symmetric matrices. Let \( J \subseteq S^n \) be a closed convex cone and \( Q, H \in S^n \). We use \( \text{COP}(K \cap J, Q, H) \) for \( \text{COP}(K \cap J) \) and \( \zeta_p(K \cap J, Q, H) \) for \( \zeta_p(K \cap J) \) to display their dependency on \( Q \in S^n \) and \( H \in S^n \). Similarly, \( \text{COP}(J, Q, H) \) for \( \text{COP}(J) \), \( \zeta_p(J, Q, H) \) for \( \zeta_p(J) \), \( \text{DCOP}(J, Q, H) \) for \( \text{DCOP}(J) \), and \( \zeta_d(J, Q, H) \) for \( \zeta_d(J) \).

\( \text{COP}(K \cap J, Q, H) \) represents a general (or extended) quadratically constrained quadratic program (QCQP)

\[
\zeta_p(K \cap J, Q, H) = \inf \{ x^T Q x : x \in \mathbb{R}^n, x x^T \in J, x^T H x = 1 \},
\]

and \( \text{COP}(J, Q, H) \) its semidefinite programming (SDP) relaxation. Recall that Theorem 1.2 (i) states a necessary and sufficient condition

\[ J = \text{co} K' \] for some \( K' \subset K = \bigcup \{ \text{all extreme rays of } S^n_+ \} \)

for \( J \in \hat{F}(K) \), and Theorem 3.5 (iii) describes a necessary condition

\[ \text{every extreme ray of } J \text{ lies in } K \]

for \( J \in \hat{F}(K) \). See Figures 2 in Section 3. These two conditions are independent from the description of \( J \). When applying to QCQPs, however, \( J \) is usually described in terms of inequalities \( \langle B_k, X \rangle \leq 0 \) and/or equalities \( \langle B_k, X \rangle = 0 \) with \( B_k \in S^n \) \( (1 \leq k \leq m) \). In this section, we focus on the cases where \( J = \{ X \in S^n_+ : \langle B_k, X \rangle \leq 0 \} \) \( (1 \leq k \leq m) \}, and present a sufficient condition on \( B_k \in S^n \) \( (1 \leq k \leq m) \} \) for \( J \in \hat{F}(K) \). The condition should be sufficient for the above mentioned conditions to hold.

For each \( B \in S^n \), let

\[ J_0(B) = \{ X \in S^n_+ : \langle B, X \rangle = 0 \}, \] \( J_-(B) = \{ X \in S^n_+ : \langle B, X \rangle \leq 0 \}. \]

Let \( m \) be a nonnegative integer, \( Q, H, B_1, \ldots, B_m \in S^n \), and \( J_- = \bigcap_{k=1}^m J_-(B_k) \). We note that \( J_- = S^n_+ \) \( \in \hat{F}(K) \) if \( m = 0 \). We consider \( \text{COP}(K \cap J_-, Q, H) \) and its convex relaxation \( \text{COP}(J_-, Q, H) \). We can rewrite \( \text{COP}(K \cap J_-, Q, H) \) as a QCQP:

\[
\zeta_p(K \cap J_-, Q, H) = \inf \left\{ x^T Q x : x \in \mathbb{R}^n, x^T B_k x \leq 0 \text{ (1 \leq k \leq m), } x^T H x = 1 \right\}. \tag{7}
\]

\( \text{COP}(J_-, Q, H) \) serves as an SDP relaxation of the QCQP \( (7) \). We establish the following result.
Theorem 4.1. Assume that

\[ J_0(B_k) \subseteq J_- \equiv \cap_{\ell=1}^m J_-(B_\ell) \quad (1 \leq k \leq m). \tag{8} \]

(See Figure 1 in Section 1). Then,

(i) \( J_- \in \hat{F}(K) \).

(ii) Let \( Q \in S^n \) and \( H \in S^n \). Then \(- \infty < \zeta_p(J_-, Q, H) = \zeta_p(K \cap J_-, Q, H) < \infty \) iff \(- \infty < \zeta_p(J_-, Q, H) < \infty \).

We provide some illustrative examples in Section 4.1, before presenting a proof of the theorem in Section 4.2. If \( m = 0 \) or \( 1 \), then assumption (8) obviously holds. Suppose that \( m \geq 2 \). Then, the assumption (8) can be rewritten as \( \langle B_\ell, X \rangle \leq 0 \) if \( \langle B_k, X \rangle = 0 \) and \( X \in S^n_+ \) \((1 \leq k, \ell \leq m, k \neq \ell)\), or equivalently,

\[-B_\ell - B_k \tau \in S^n_+ \text{ for some } \tau \in \mathbb{R} \quad (1 \leq k, \ell \leq m, k \neq \ell), \tag{9}\]

where \( \tau \) can depend on both \( k \) and \( \ell \). (For the equivalence, consider the SDP of minimizing \( \langle -B_\ell, X \rangle \) subject to \( \langle B_k, X \rangle = 0 \) in \( X \in S^n_+ \) and its dual). If \( \tau \leq 0 \) in \( \langle -B_\ell, X \rangle \leq 0 \) for every \( X \in S^n_+ \) satisfying \( \langle B_k, X \rangle \leq 0 \); hence the constraint \( \langle B_\ell, X \rangle \leq 0 \) (or \( J_-(B_\ell) \)) is redundant. If we assume that none of the constraints \( \langle B_k, X \rangle \leq 0 \) \((1 \leq k \leq m)\) is redundant, then \( \langle -B_\ell, X \rangle \leq 0 \) \((1 \leq k \leq m, k \neq \ell)\) can be replaced by

\[-B_\ell - B_k \tau \in S^n_+ \text{ for some } \tau > 0 \quad (1 \leq k, \ell \leq m, k \neq \ell), \tag{10}\]

which implies \( \inf \{ \langle -B_\ell, X \rangle : X \in S^n_+, \langle B_k, X \rangle \geq 0 \} \geq 0 \) \((1 \leq k \leq m, \ell \neq k)\) i.e.,

\[ J_+(B_k) \equiv \{ X \in S^n_+ : \langle B_k, X \rangle \geq 0 \} \subseteq J_- \quad (1 \leq k \leq m) \]

(See Figure 1 in Section 1). A trivial sufficient condition for \( \langle -B_\ell, X \rangle \leq 0 \) \((1 \leq k \leq m)\) is

\[ \langle B_k + B_\ell, X \rangle \leq 0 \text{ for every } X \in S^n_+ \text{ or } - (B_k + B_\ell) \in S^n_+ \quad (1 \leq k < \ell \leq m), \tag{11}\]

which is easy to check in the examples below.

In Section 4.3, we prove the following result.

Theorem 4.2. Let \( B \in S^n \).

(i) \( J_0(B) \in \hat{F}(K) \) and \( J_-(B) \in \hat{F}(K) \) are equivalent.

(ii) \( J_0(B) \in \hat{F}(K) \).

In Section 4.4, we briefly discuss how multiple equality constraints can be added to QC-QPs \( \langle 7 \rangle \).
4.1 Some examples

We present six examples.

**Example 4.3.** If \( m = 1 \), then (8) is satisfied for any \( B_1 \in \mathbb{S}^n \). Let \( Q_0, \ Q_1, \ Q_2 \in \mathbb{S}^n \). Consider the QCQP

\[
\zeta_{\text{QCQP}} = \inf \left\{ u^T Q_0 u : u \in \mathbb{R}^\ell, u^T Q_1 u \leq 1, \ u^T Q_2 u \leq 1 \right\}.
\]

This form of QCQP was studied in [17, 23]. They showed that QCQP (12) can be solved by its SDP relaxation under strong duality of its SDP relaxation, which is not assumed here. We can transform QCQP (12) into

\[
\eta_{\text{QCQP}} = \inf \left\{ u^T Q_0 u : u \in \mathbb{R}^\ell, u^T Q_1 u \leq 1, \ u^T Q_2 u + u_{\ell+1}^2 \right\} = \inf \left\{ u^T Q_0 u : u \in \mathbb{R}^\ell, \ u^T (Q_1 - Q_2) u - u_{\ell+1}^2 \leq 0, \ u^T Q_2 u + u_{\ell+1}^2 = 1 \right\} = \zeta_p(\mathbb{J}_-, Q, H) \text{ (with } m = 1),
\]

where \( n = \ell + 1 \),

\[
x = \begin{pmatrix} u \\ u_{\ell+1} \end{pmatrix}, \quad Q = \begin{pmatrix} Q_0 & 0 \\ 0 & 0 \end{pmatrix}, \quad B_1 = \begin{pmatrix} Q_1 - Q_2 & 0 \\ 0 & -1 \end{pmatrix}, \quad H = \begin{pmatrix} Q_2 & 0 \\ 0 & 1 \end{pmatrix}.
\]

Thus, condition (8) is satisfied with \( m = 1 \).

**Example 4.4.** Let \( Q, \ H, \ B \in \mathbb{S}^n \). Consider a QCQP with two equality constraints.

\[
\eta_{\text{QCQP}} = \begin{cases} x^T Q x : x^T B x = 1, \ x^T H x = 1 \\ x^T Q x : x^T (B - H) x = 0, \ x^T H x = 1 \end{cases} = \zeta_p(\mathbb{J}_0(B_1), Q, H),
\]

where \( B_1 = B - H \). By Theorem 4.2 (ii), \( \mathbb{J}_0(B_1) \in \mathcal{F}(\mathbb{R}) \). We can also rewrite the QCQP as

\[
\eta_{\text{QCQP}} = \begin{cases} x^T Q x : x^T (B_1) x \leq 0, \ x^T (B_2) x \leq 0, \ x^T H x = 1 \end{cases},
\]

where \( B_2 = -(B - H) \). Then \( -(B_1 + B_2) = O \in \mathbb{S}^n_+ \); hence (11) holds with \( m = 2 \). This also shows that \( \mathbb{J}_0(B_1) = \mathbb{J}_-(B_1) \cap \mathbb{J}_-(B_1) \in \mathcal{F}(\mathbb{R}) \) for every \( B_1 \in \mathbb{S}^n \).

**Example 4.5.** Let \( q_k(u) = u^T Q_k u + 2b_k^T u \) be a quadratic function in \( u \in \mathbb{R}^\ell \), where \( Q_k \in \mathbb{S}^\ell, b_k \in \mathbb{R}^\ell (k = 0, 1) \). Consider a QCQP:

\[
\zeta_{\text{QCQP}} = \inf \left\{ q_0(u) : u \in \mathbb{R}^\ell, -1 \leq q_1(u) \leq 1 \right\}.
\]

This type of QCQP was studied in [21] in connection with indefinite trust region subproblems. See also [10, 23]. QCQP (13) can be rewritten as

\[
\eta_{\text{QCQP}} = \inf \left\{ u^T Q_0 u + 2b_0^T uu_{\ell+1} : \ -u^T Q_1 u - 2b_1^T uu_{\ell+1} - u_{\ell+1}^2 \leq 0, \ u^T Q_1 u + 2b_1^T uu_{\ell+1} - u_{\ell+1}^2 \leq 0 \right\} = \zeta_p(\mathbb{J}_-, Q, H) \text{ (with } m = 2),
\]
where \( n = \ell + 1 \),
\[
\begin{align*}
x &= \begin{pmatrix} u \\ u_{\ell+1} \end{pmatrix}, \quad Q = \begin{pmatrix} Q_0 & b_0 \\ b_0^T & 0 \end{pmatrix}, \\
B_1 &= \begin{pmatrix} -Q_1 & b_1 \\ -b_1^T & -1 \end{pmatrix}, \quad B_2 = \begin{pmatrix} Q_1 & b_1 \\ b_1^T & -1 \end{pmatrix}, \quad H = \begin{pmatrix} O & 0 \\ 0^T & 1 \end{pmatrix}.
\end{align*}
\]

It is easy to verify that
\[
\langle B_1, X \rangle + \langle B_2, X \rangle = -2X_{nm} \leq 0 \text{ for every } X \in \mathbb{S}_+^n. \tag{14}
\]

Therefore, condition \([11]\) is satisfied with \( m = 2 \).

**Example 4.6.** We add the constraint \( \|u\|^2 / \gamma \geq \gamma \) to QCQP \([13]\) in Example 4.5 where \( \gamma > 0 \) is a parameter determined later. Then, the resulting QCQP can be written as
\[
\eta_{\text{QCQP}} = \inf \left\{ q_0(u) : u \in \mathbb{R}^\ell, -1 \leq q_1(u) \leq 1, \|u\|^2 / \gamma \geq \gamma \right\} = \inf \left\{ x^T Q x : x^T B_k x \leq 0 \ (k = 1, 2, 3), x^T H x = 1 \right\}, \tag{15}
\]

where \( n, x, Q, B_1, B_2 \) and \( H \) are the same as in Example 4.5 and \( B_3 = \begin{pmatrix} -I/\gamma & 0 \\ 0 & \gamma \end{pmatrix} \). In addition to \([14]\),
\[
\begin{align*}
\langle B_1, X \rangle + \langle B_3, X \rangle &= \langle \begin{pmatrix} -Q_1 & -I/\gamma \\ -b_1^T & -1 + \gamma \end{pmatrix}, X \rangle \leq 0 \text{ for every } X \in \mathbb{S}_+^n, \\
\langle B_2, X \rangle + \langle B_3, X \rangle &= \langle \begin{pmatrix} Q_1 & -I/\gamma \\ b_1^T & -1 + \gamma \end{pmatrix}, X \rangle \leq 0 \text{ for every } X \in \mathbb{S}_+^n.
\end{align*}
\]

hold if we take a sufficiently small \( \gamma > 0 \). Therefore, condition \([11]\) is satisfied with \( m = 3 \).

Adding the constraint \( \|u\|^2 / \gamma \geq \gamma \) to QCQP \([13]\) is interpreted as removing the ball \( \{ u \in \mathbb{R}^n : \|u\| / \gamma < \gamma \} \) with the center 0, which lies the interior of the feasible region, from the feasible region. The above result implies that if the size of the ball is sufficiently small then we can remove the ball from the feasible region without destroying \( \mathbb{J} \subset \bar{F}(\mathbb{K}) \).

For example, suppose that \( Q_1 = O \) and \( b_1 = \begin{pmatrix} 0 \\ 1/2 \end{pmatrix} \in \mathbb{R}^\ell \). Then QCQP \([13]\) turns out to be
\[
\eta_{\text{QCQP}} = \inf \left\{ q_0(u) : u \in \mathbb{R}^\ell, -1 \leq u_\ell \leq 1, \|u\|^2 / \gamma \geq \gamma \right\}.
\]

In this case, if \( 0 < \gamma \leq 4/5 \), then \([16]\) is satisfied. It is interesting to note that the unit ball \( \{ u \in \mathbb{R}^\ell : \|u\| \leq 1 \} \) is included in \( \{ u \in \mathbb{R}^\ell : -1 \leq u_\ell \leq 1 \} \), but we cannot take \( \gamma = 1 \) to satisfy \([16]\).

**Example 4.7.** Let \( B_k \) be a matrix in \( \mathbb{S}_+^n \) whose elements satisfy
\[
[B_k]_{ij} = [B_k]_{ji} \in \begin{cases} (-\infty, 1] & \text{if } i = j = k, \\
(\infty, -2] & \text{if } i = j \neq k, \\
[-1/(2n), 1/(2n)] & \text{otherwise}.
\end{cases}
\]

\((k = 1, \ldots, n)\). Then,
\[
-(B_k + B_\ell) = -(B_k + B_\ell) \in \begin{cases} [1, \infty) & \text{if } i = j, \\
[-1/n, 1/n] & \text{otherwise},
\end{cases}
\]

which implies that \(-(B_k + B_\ell)\) is diagonally dominant; hence positive semidefinite \((1 \leq k < \ell \leq n)\). Therefore, condition \([11]\) is satisfied with \( m = n \).
Example 4.8. Let \( A \) be an \( r \times n \) matrix. Adding a homogeneous linear equality constraint \( Ax = 0 \) to QCQP \( (7) \), we have

\[
\tilde{\eta}_{\text{QCP}} = \inf \left\{ x^TQx : \begin{array}{l}
x \in \mathbb{R}^n, \quad x^TB_i x \leq 0 \quad (1 \leq k \leq m), \\
x^T H x = 1, \quad Ax = 0 \end{array} \right\} 
= \inf \left\{ \langle Q, X \rangle : X \in \mathbb{K} \cap \mathbb{J} \cap \mathbb{F} \right\} = \zeta_p(\mathbb{K} \cap \mathbb{J} \cap \mathbb{F}, Q, H),
\]

where \( \mathbb{F} \equiv \{ X \in \mathbb{S}^n_+ : \langle A^T A, X \rangle = 0 \} \) forms a face of \( \mathbb{S}^n_+ \) since \( A^T A \in \mathbb{S}^n_+ \). By Theorem 3.5 (ii), \( \mathbb{J} \cap \mathbb{F} \in \hat{\mathcal{F}}(\mathbb{K}) \) if \( \mathbb{J} \in \hat{\mathcal{F}}(\mathbb{K}) \). Therefore, we can add \( Ax = 0 \) to any of the examples above so that the resulting QCQP can still be solved exactly by its SDP relaxation as long as \( -\infty < \zeta_p(\mathbb{J} \cap \mathbb{F}, Q, H) < \infty \).

4.2 Proof of Theorem 4.1

We need the following lemma.

Lemma 4.9. ([23, Lemma 2.2]) Let \( B \in \mathbb{S}^n \) and \( X \in \mathbb{S}^n_+ \) with \( \text{rank} X = r \). Suppose that \( \langle B, X \rangle \leq 0 \). Then, there exists a rank-1 decomposition of \( X \) such that \( X = \sum_{i=1}^r x_ix_i^T \) and \( x_i^T B x_i \leq 0 \) \((1 \leq i \leq r)\). If, in particular, \( \langle B, X \rangle = 0 \), then \( x_i^T B x_i = 0 \) \((1 \leq i \leq r)\).

Proof Theorem 4.1 (i): For the proof, we utilize Theorem 1.2 (iii) and Lemma 4.9. Choose a \( Q \in \mathbb{S}^n \) arbitrarily, and consider COP\( (\mathbb{J}, Q, I) \). We first observe that the feasible region of COP\( (\mathbb{J}, Q, I) \) is either empty or bounded since every feasible \( X \) satisfies \( X \in \mathbb{S}^n_+ \) and \( \langle I, X \rangle = 1 \). If \( \mathbb{J} = \{0\} \), then the feasible region of COP\( (\mathbb{J}, Q, I) \) is empty; hence \( \zeta_p(\mathbb{J}, Q, I) = \zeta_p(\mathbb{K} \cap \mathbb{J}, Q, I) = \infty \). Otherwise, there exists a nonzero \( X \in \mathbb{J} \subseteq \mathbb{S}^n_+ \), and \( X/\langle I, X \rangle \) lies in the feasible region. Hence, the feasible region is bounded, and COP\( (\mathbb{J}, Q, I) \) has a nonzero optimal solution with a finite optimal value \( \zeta_p(\mathbb{J}, Q, I) \).

Obviously \( I \in \mathbb{S}^n_+ \subseteq \mathbb{J}^* \). By Theorem 2.3 DCOP\( (\mathbb{J}, Q, I) \) has an optimal solution \( (\hat{i}, \hat{Y}) \) such that

\[
0 = \zeta_p(\mathbb{J}, Q, I) - \zeta_p(\mathbb{J}, Q, I) = \langle X, \overline{Y} \rangle
\]

for every optimal solutions \( X \) of COP\( (\mathbb{J}, Q, I) \). The following two cases occur. Case (a): there exists a nonzero optimal solution \( X \) and a \( k \in \{1, \ldots, m\} \) such that \( X \in \mathbb{J}_0(B_k) \), i.e., \( \langle B_k, X \rangle = 0 \). Case (b): \( \langle B_k, X \rangle < 0 \) for all optimal solutions of COP\( (\mathbb{J}, Q, I) \) and all \( k \in \{1, \ldots, m\} \).

Case (a): Let \( r = \text{rank} X \). By Lemma 4.9, there exists a rank-1 decomposition of \( X \) such that \( X = \sum_{i=1}^r x_ix_i^T \) and \( x_i^T B_k x_i = 0 \) \((1 \leq i \leq r)\). Since \( 1 = \langle I, X \rangle = \sum_{i=1}^r x_i^T x_i \), there exist a \( \tau \in (0, 1] \) and a \( j \in \{1, \ldots, r\} \) such that \( x_j^T x_j = \tau \). Let \( \vec{x} = x_j/\sqrt{\tau} \) and \( \overline{X} = \vec{x} \vec{x}^T \). Then \( \langle B_k, \overline{X} \rangle = \vec{x}_j^T B_k \vec{x}_j/\tau = 0 \); hence \( \overline{X} \in \mathbb{J}_0(B_k) \). By assumption \( [8] \), \( \overline{X} \in \mathbb{J} \). We also see that \( \langle I, \overline{X} \rangle = \langle I, x_jx_j^T/\tau \rangle = 1 \). Hence \( \overline{X} \) is a rank-1 feasible solution of COP\( (\mathbb{J}, Q, I) \). Furthermore, we see that

\[
0 \leq \langle \overline{X}, \overline{Y} \rangle = \frac{\langle x_jx_j^T/\tau, \overline{Y} \rangle}{\tau} \leq \frac{\langle X, \overline{Y} \rangle}{\tau} = 0.
\]

Hence, \( \overline{X} \) is a rank-1 optimal solution of COP\( (\mathbb{J}, Q, I) \), and it is an optimal solution of COP\( (\mathbb{K} \cap \mathbb{J}, Q, I) \) with the same objective value \( \langle Q, X \rangle \). Therefore, we have shown that \( \zeta_p(\mathbb{J}, Q, I) = \zeta_p(\mathbb{K} \cap \mathbb{J}, Q, I) \).
Case (b): Let $S$ denote the optimal solution set of COP($\mathbb{J}_-, Q, I$). By the assumption of this case, $\langle B_k, X \rangle < 0$ $(1 \leq k \leq m)$ for all $X \in S$. Hence $S$ coincides with the optimal solution set of COP($\mathbb{S}_n^+, Q, I$), an SDP of minimizing $\langle Q, X \rangle$ subject to $X \in \mathbb{S}_n^+$ and the single equality constraint $\langle H, X \rangle = 1$. It is well-known that every solvable SDP with $r$ equality constraints has an optimal solution $X$ with rank $\leq \sqrt{2r}$ (see, for example, [15]). Hence, there exists an $\overline{X} \in S$ such that rank$\overline{X} = 1$, which is a common optimal solution of COP($\mathbb{J}_-, Q, I$) and COP($\mathcal{K} \cap \mathbb{J}_-, Q, I$). Therefore, $\zeta_p(\mathbb{J}_-, Q, I) = \zeta_p(\mathcal{K} \cap \mathbb{J}_-, Q, I)$.

In both Cases (a) and (b), we have shown that $\zeta_p(\mathbb{J}_-, Q, I) = \zeta_p(\mathcal{K} \cap \mathbb{J}_-, Q, I)$. Since $Q$ is chosen arbitrarily from $\mathbb{S}_n^+$, we can conclude by Theorem [1.2][iii] that $\mathbb{J}_- \in \mathcal{F}(\mathcal{K})$. \hfill \Box

**Proof Theorem 4.2 (ii):** The desired result follows from Corollary 2.2. \hfill \Box

### 4.3 Proof of Theorem 4.2

(i) We first show that $\mathbb{J}_0(B) \in \mathcal{F}(\mathcal{K}) \Rightarrow \mathbb{J}_-(B) \in \mathcal{F}(\mathcal{K})$. Since $\mathbb{J}_-(B)$ is a convex set containing $\mathcal{K} \cap \mathbb{J}_-(B)$, $\text{co}(\mathcal{K} \cap \mathbb{J}_-(B)) \subset \mathbb{J}_-(B)$ is obvious. To show $\mathbb{J}_-(B) \subset \text{co}(\mathcal{K} \cap \mathbb{J}_-(B))$, let $X \in \mathbb{J}_-(B)$. Then there exists an $X^i \in \mathcal{K}$ such that

$$X = \sum_{i=1}^{m} X^i, \quad 0 \geq \langle B, X \rangle = \sum_{i=1}^{m} \langle B, X^i \rangle.$$ 

Let $I_+ = \{i : \langle B, X^i \rangle > 0\}$ and $I_0 = \{i : \langle B, X^i \rangle = 0\}$, $I_- = \{i : \langle B, X^i \rangle < 0\}$. By definition, $X^i \in \mathcal{K} \cap \mathbb{J}_-(B)$ $(i \in I_0 \cup I_-)$. Hence, if $I_+ = \emptyset$ then $X \in \text{co}(\mathcal{K} \cap \mathbb{J}_-(B))$.

Now assume that $I_+ \neq \emptyset$. Then, $I_- \neq \emptyset$ since otherwise $\langle B, X \rangle = \sum_{i=1}^{m} \langle B, X^i \rangle > 0$, a contradiction. Let

$$X^+ = \sum_{i \in I_+} X^i, \quad X^0 = \begin{cases} \sum_{i \in I_0} X^i & \text{if } I_0 \neq \emptyset, \\ 0 & \text{otherwise} \end{cases}, \quad X^- = \sum_{i \in I_-} X^i.$$ 

Then,

$$X^0 \in \text{co}(\mathcal{K} \cap \mathbb{J}_0(B)), \quad X^- \in \text{co}(\mathcal{K} \cap \mathbb{J}_0(B)), \quad X = X^+ + X^0 + X^-,$$ 

$$\alpha^+ \equiv \langle B, X^+ \rangle > 0, \quad \alpha^0 \equiv \langle B, X^0 \rangle = 0, \quad \alpha^- \equiv -\langle B, X^- \rangle > 0,$$ 

$$0 \geq \langle B, X \rangle = \langle B, X^+ + X^0 + X^- \rangle = \alpha^+ - \alpha^-.$$ 

Define

$$X \equiv \frac{\alpha^- X^+ + \alpha^+ X^-}{\alpha^+ + \alpha^-}, \quad \text{which implies } X^+ = \frac{\alpha^+ + \alpha^-}{\alpha^-} X - \frac{\alpha^+}{\alpha^-} X^-.$$ 

Then,

$$\overline{X} \in \text{co} \mathcal{K}, \quad \langle B, \overline{X} \rangle = \frac{\alpha^- \langle B, X^+ \rangle + \alpha^+ \langle B, X^- \rangle}{\alpha^+ + \alpha^-} = \frac{\alpha^- \alpha^+ - \alpha^+ \alpha^-}{\alpha^+ + \alpha^-} = 0.$$ 

Hence, $\overline{X} \in \mathbb{J}_0(B) = \text{co}(\mathcal{K} \cap \mathbb{J}_0(B)) \subset \text{co}(\mathcal{K} \cap \mathbb{J}_-(B))$. It follows from (17) and (19) that

$$X = X^+ + X^0 + X^- = \frac{\alpha^+ + \alpha^-}{\alpha^-} \overline{X} + \frac{\alpha^- - \alpha^+}{\alpha^-} X^- + X^0.$$ 

17
Since we have already shown that the three points $X, X^0$ and $X^-$ lies in $\operatorname{co}(K \cap \mathbb{J}(B))$ and $\alpha^+ - \alpha^- \geq 0$ and $\alpha^0 - \alpha^- \geq 0$ (by (18)), we obtain $X \in \operatorname{co}(K \cap \mathbb{J}(B))$. Thus we have shown that $J_0(B) \in \hat{F}(K) \Rightarrow J_-(B) \in F(K)$.

We show that $J_0(B) \in \hat{F}(K) \iff J_-(B) \in \hat{F}(K)$. It is easy to verify that $J_0(B)$ is a face of $J_-(B) \in \hat{F}(K)$. Then $J_0(B) \in \hat{F}(K)$ follows by Theorem 3.5 (i). We also know that $J_0(B) = J_-(B) \cap J_-(B) \in \hat{F}(K)$ (see Example 4.4). Therefore, we have shown that $J_0(B) \in \hat{F}(K) \iff J_-(B) \in \hat{F}(K)$.

(ii) Since $J_0(B) \in \hat{F}(K)$ is equivalent to $J_-(B) \in \hat{F}(K)$ by (i), $J_0(B) \in \hat{F}(K)$ follows from Theorem 4.1 (i) with $m = 1$.

Remark 4.10. Assertion (i) of Theorem 4.2 holds for a more general case where $K$ is a cone in a finite dimensional space $V$ and $B \in V$. Define

$$
J_0(B) = \{ X \in coK : \langle B, X \rangle = 0 \},
$$

Then, $J_0(B) \in \hat{F}(K)$ and $J_-(B) \in \hat{F}(K)$ are equivalent. The proof of Theorem 4.2 (i) stated above remains valid for this general case without any change.

### 4.4 Adding equality constraints

Assume that, in general,

$$
J \equiv \{ X \in S^n : \langle B_j, X \rangle = 0 \ (j \in I_0), \ \langle B_k, X \rangle \leq 0 \ (k \in I_-) \} \in \hat{F}(K),
$$

where $I_0$ and $I_-$ denote a partition of $\{1, \ldots, m\}$ and $Q, H, B_k \in S^n$ ($k \in I_0 \cup I_-$). We present a method for adding an equality constraint $\langle B_{m+1}, X \rangle = 0$ to $J$ so that $J \cap J_0(B_{m+1})$ remains in $\hat{F}(K)$. The method can be used recursively by replacing $I_0$ with $I_0 \cup \{m+1\}$. Note that $I_-$ is not updated. Initially, we take $J_- \equiv \cap_{k=1}^{m} J_-(B_k)$ with $B_k \in S^n$ ($1 \leq k \leq m$) satisfying (8) or $J_0(B_1)$ with $B_1 \in S^n$ for $J$; hence if $I_- \neq \emptyset$, then conditions (8) and (9) hold.

If $I_0 = \emptyset$, we can choose any $B \in S^n$ satisfying $J_0(B) \subseteq J_-(B_k)$ ($k \in I_-$) so that $J_- \cap J_0(B) = J_0(B) \in \hat{F}(K)$ by Theorem 4.2 (i). As a result, all inequality constraints $\langle B_k, X \rangle$ ($k \in I_-$) become redundant. We exclude this trivial choice in the subsequent discussion.

Let $K' = K \cap J$, which is a cone in $S^n$. It follows from $J \in \hat{F}(K)$ that $\operatorname{co}(K' \cap J) = \operatorname{co}(K \cap J)$. Hence $J \in \hat{F}(K')$. All the results in Section 3 is quite general so that the results can be applied even if $K$ is replaced with $K'$ and $S^+_n = \operatorname{co}K$ with $\operatorname{co}K'$. However, it is difficult to extend Theorems 1.1 and 1.2 to the general case where $S^+_n$ is replaced with $\operatorname{co}(K' \cap J)$ defined by (20). The main reason is that Lemma 4.9 is no longer valid for the general case. Consequently, it becomes clear that adding an equality constraint to $J$ is more restrictive than adding inequalities as only the general results in Section 3 can be used.

Given a $B \in S^n$, we utilize the following two facts to check whether $J \cap J_0(B) \in \hat{F}(K)$. The first one is that if $J_0(B)$ is a face of $J \in \hat{F}(K)$, then $J \cap J_0(B) \in \hat{F}(K')$ (Theorem 3.5 (i)), where $K' = K \cap J$. The other is that $J_0(B)$ is a face of $J$ if

$$
B \in J^* = \left\{ Z \in S^n : \sum_{j \in I_- \cup I_0} B_j y_j \in S^+_n \right\},
$$

for some $y \in \mathbb{R}^m$ such that $y_k \leq 0$ ($k \in I_-$).
Obviously, \( \{O\} \in J^* \). However, if we take \( B = \{O\} \), then \( J_0(B) = \mathbb{S}_+^n \); hence \( J \cap J_0(B) = J \). Also if \( B \in J^* \) is positive definite then \( J_0(B) = \{O\} \); hence \( J \cap J_0(B) = \{O\} \) and COP(\( J \cap J_0(B) \), \( Q \), \( H \)) becomes infeasible. Therefore, we need to avoid these two cases.

We show three representative cases where \( B \in J^* \) holds. Obviously, every \( B \in \mathbb{S}_+^n \) lies in \( J^* \). In this case, \( J_0(B) \) forms a common face of \( J \) and \( \mathbb{S}_+^n \). It is also easy to see that \( B = -B_k \in J^* \) for every \( k \in I_- \). In this case, \( J \cap J_0(-B_k) = (\cap_{j \in I_0} J_0(B_j)) \cap J_0(B_k) \) and all inequalities \( \langle B_k, X \rangle \leq 0 \) (\( k \in I_- \)) become redundant. (Recall that assumption (8) holds if \( I_- \neq \emptyset \)). Now, consider the third case. Let \( k, \ell \in I_- = \{1, \ldots, m\} \). Then (9) holds. Hence \( B = -B_k - B_{\ell} \tau \) satisfies \( \mathbb{S}_+^n \ni O = B - \sum_{j \in I_- \cup I_0} B_j y_j \) with \( y_k = -1, y_\ell = -\tau \) and \( y_j = 0 \) (\( j \neq k, \ j \neq \ell \)). Therefore, \( B \in J^* \), and \( J \cap J_0(B) \in \mathcal{F}(K) \) follows.

5 Concluding discussion

By extending the condition \( \text{co}(K \cap J) = J \) with a face \( J \) of \( \text{co}K \) in [14] to characterizations of the family \( \mathcal{F}(K) \) of all convex cone \( J \subseteq \text{co}K \) satisfying \( \text{co}(K \cap J) = J \), we have established the fundamental properties of \( \mathcal{F}(K) \) in Section 3. In particular, by applying the properties to nonconvex QCQPs, we have shown that a new class of QCQP with multiple nonconvex inequality and equality constraints can be solved exactly by its SDP relaxation in Section 4.

The important and distinctive feature of the geometric nonconvex COP(\( K \cap J \)) and its convex conic reformulation COP(\( J \)) is independence from the description of \( K \) and \( J \). The required main assumption is that \( K \) is a cone in \( V \) and \( J \in \mathcal{F}(K) \), which indicates that the results presented in Sections 2 and 3 can be applied in various cases. It should be noted that the other assumption \( -\infty < \zeta_p(J) < \infty \) is necessary and sufficient to ensure \( \zeta_\varphi(J) = \zeta_\varphi(K \cap J) \) under \( J \in \mathcal{F}(K) \). We have not imposed any assumption on the objective function \( \langle Q, X \rangle \). See Corollary 2.2.

To the question of whether Theorem 4.1 can be applied to the completely positive relaxation of QCQPs, we should note that the answer is negative, as shown in the following simple example: Let \( K = \{xx^T : x \in \mathbb{R}_+^2\} \) and \( J_0 = \{X \in \text{co}K : X_{11} - X_{22} = 0\} \). Then \( \text{co}(K \cap J_0) = \left\{ \lambda \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} : \lambda \geq 0 \right\} \) is a proper subset of \( J_0 \); hence \( J_0 \notin \mathcal{F}(K) \). Thus assertion (ii) of Theorem 4.2 does not hold for this case. Or, at least, some modification is necessary on assumption (8). This example also shows that Lemma 4.9 is no longer valid if \( \mathbb{S}_+^n \) is replaced with the completely positive cone.
